
ORNITHIÆ, a name given by the ancients to certain winds, which uſually blew in ſpring, at the time when the birds of paſſage came over to them. Pliny ſays, that theſe winds blew from the weſt, and that, by ſome, the Eteſian winds were called by this name. Others ſuppoſe that they blew from the north, or north-weſt.

ORNITHOGALUM, in *Botany*, an ancient name, adopted by the Latins from the Greeks, evidently derived from ορνις, ορνιθος, *a bird*, and γαλα, *milk*; but its application has proved a ſtumbling block to moſt etymologiſts. Ambroſinus preſumes the word may allude, either to the ſhining milky white of the flowers, like that of a hen's egg; or to the white egg-ſhaped bulbs. Tournefort ſuppoſes the flowers, being green when cloſed, and white when expanded, may have been compared to the wings of ſeveral birds. Linnæus firſt gave the true explanation, in ſuggeſting, (*Mant.* 364. *Prælect. in Ord. Nat.* 287), that the *O. umbellatum* appears to be the "doves' dung," mentioned in the 2d book of Kings, chap. vi. v. 25, as having fetched ſo high a price during the ſiege of Samaria. It is recorded by the ſacred writer, that a quarter of a cab of dove's dung then ſold for five pieces of ſilver; and the rabbinical commentators, taking the words literally, have aſſerted, abſurdly enough, that it was uſed as fuel. As the plant grows copiouſly in Paleſtine, whence the Engliſh name, ſtar of Bethlehem, and the roots are ſtill in common uſe for food in that country, the name is explained by the reſemblance in the colours of the flower to the dung of birds, the white or milky part of which, their urine, is contraſted with dull green, exactly as in the petals of this original ſpecies of the genus before us, and which appears to be the very one deſcribed by Dioſcorides. The writer of the preſent article had the ſatisfaction of finding this, his own explanation of the matter, had previouſly occurred to Linnæus.—Linn. Gen. 166. Schreb. 221. Willd. Sp. Pl. v. 2. 111. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 362. Prodr. Fl. Græc. Sibth. v. 1. 229. Ait. Hort. Kew. ed. 2. v. 2. 256. Tournef. t. 203. Juſſ. 53. Lamarck Dict. v. 4. 612. Illuſtr. t. 242. Gærtn. t. 17.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Aſphodeli*, Juſſ.

Gen. Ch. *Cal.* none. *Cor.* Petals ſix, lanceolate, their lower half erect; upper ſpreading; permanent, fading. *Stam.* Filaments ſix, erect, alternately dilated at the baſe, ſhorter than the corolla; anthers ſimple. *Piſt.* Germen angulated; ſtyle awl-ſhaped, permanent; ſtigma obtuſe. *Peric.* Capſule ſuperior, roundiſh, angulated, of three cells and three valves. *Seeds* ſeveral, roundiſh.

Obſ. In ſome ſpecies the filaments are flat and erect, the alternate ones trifid at the top, their middle point bearing

bearing the anther; in others the alternate filaments are ſimple.

Eſſ. Ch. Corolla of ſix petals, erect, permanent, their upper part ſpreading. Filaments dilated at the baſe. Capſule ſuperior, of three cells. Seeds roundiſh, naked.

Obſ. Of this beautiful and extenſive genus the 14th edition of *Syſtema Vegetabilium* mentions only 22 ſpecies, diſtributed into two ſections; firſt ſuch as have all their ſtamens awl-ſhaped; ſecondly, ſuch as have the alternate ſtamens emarginate. But this arrangement is aboliſhed in Willdenow who gives 43 ſpecies, and in the 2d edition of *Hortus Kewenſis*, where 24 are mentioned. We ſhall ſelect ſeveral for the ſake of illuſtration, two of which, *arvenſe* and *nanum*, are not in Willdenow.

O. *uniflorum*. One-flowered Star of Bethlehem. Linn. Mant. 62. Laxm. in Nov. Comm. Petrop. v. 18. 529. t. 6. f. 3.—Stem with two approximated leaves. Flower ſolitary. Outer petals lanceolate, abrupt; inner twice as broad, elliptical. Found on the ſummits of ſome hills in Siberia. It flowers at Kew in May and June. This ſpecies greatly reſembles *O. luteum* in herbage, but the *flower* is ſolitary, and thrice as large, with broad *petals*, approaching to our *Melanthium flavum*. (See MELANTHIUM.) The *ſtem* is almoſt a ſpan high, bearing two lanceolate leaves, nearly oppoſite. *Petals* yellow above, green below, an inch long or more.

O. *ſpathaceum*. Sheathed Star of Bethlehem. Hayne in Uſt. Annal. faſc. 21. 11. t. 1. Willd. n. 4. Sm. Fl. Græc. Sibth. t. 331, unpubliſhed. (O. minimum; Fl. Dan. t. 612.)—Corymb ſimple, of few flowers, on ſmooth ſtalks. Bracteas lanceolate, ſlightly fringed. Leaves linear.—Native of the Levant, as well as of Germany and Denmark.—A ſmall ſpecies, with two linear, very ſlender, radical *leaves*; broad *bracteas*, one of them far below the *corymb*, and never more than three *flowers*, whoſe narrow obtuſe *petals* are yellow above, green beneath. The figure in *Fl. Dan.* makes them by far too broad and pointed.

O. *arvenſe*. Yellow Field Star of Bethlehem. Perſoon in Uſt. Annal. faſc. 11. 8. t. 1. f. 2. Sm. Fl. Græc. t. 332, unpubliſhed. (O. anguſtifolium bulbiferum; Tourn. Inſt. 379.)—Corymb compound, many-flowered, downy. Bracteas lanceolate, fringed. Leaves linear.—Frequent in the Levant.—Much larger than the laſt, with the numerous *flower-ſtalks*, and under ſide of the *petals*, downy. There are many ſmall partial *bracteas*.

O. *luteum*. Common Yellow Star of Bethlehem. Linn. Sp. Pl. 439. Engl. Bot. t. 21. Fl. Dan. t. 378.—Stalk angular, with a linear leaf at its baſe. Flower-ſtalks umbellate, ſmooth, undivided. Petals lanceolate.—Occaſionally found early in the ſpring, about woods and paſtures in Oxfordſhire, Yorkſhire, and ſome other parts of England, as well as on the continent. The *ſtem*, or rather *ſtalk*, is triangular, near a ſpan high. *Leaves* keeled, linear-lanceolate, radical, and moſtly ſolitary. *Bracteas* two, unequal, fringed, broadiſh. *Umbel* ſmooth, of ſeveral *flowers*, coloured as in the two foregoing.

O. *nanum*. Dwarf White Star of Bethlehem. Sm. Prodr. Fl. Græc. Sibth. v. 1. 230. Fl. Græc. t. 333, unpubliſhed. (O. humifuſum, floribus umbellatis albis; Buxb. Cent. 2. 35. t. 37. f. 1.)—Corymb ſimple, ſmooth, longer than its ſtalk, of few flowers. Bracteas inflated, membranous. Leaves linear, numerous.—Gathered by Dr. J. Sibthorp in Arcadia, as well as near Abydos, flowering in March. The *bulb* is as big as a hazel-nut. *Leaves* ſix or more, widely ſpreading, ſix inches long, narrow, rather glaucous. *Stalk* very ſhort, bearing two or three large, erect, white *flowers*, ribbed with green, three of whoſe *ſtamens* are dilated at the baſe.

O. *umbellatum*. Common Star of Bethlehem. Linn. Sp. Pl. 441. Engl. Bot. t. 130. Jacq. Auſtr. t. 343. Redout. Liliac. t. 143.—Corymb ſimple, many-flowered, its lower ſtalks riſing above the reſt. Filaments tapering, entire.—Not unfrequent in meadows, paſtures and groves in England, flowering in April and May. Dr. Sibthorp found it abundantly in the fields of Greece, nor does this ſpecies ſeem to be rare throughout the Levant. It is unqueſtionably the ορνιθογαλον of Dioſcorides, and we have already explained that name. With us it is frequent in gardens, conſpicuous in the ſpring for its large umbel-like *corymb* of ſhining white ſtarry *bloſſoms*, green at the back. The *roots* are eaten boiled, chiefly by poor people, in the Levant.

O. *pyrenaicum*. Spiked Star of Bethlehem. Linn. Sp. Pl. 440. Engl. Bot. t. 499. Jacq. Auſtr. t. 103. Redout. Liliac. t. 234.—Cluſter very long. Petals linear, obtuſe. Filaments all dilated. Style the length of the ſtamens. Partial flower-ſtalks equal, ſpreading; ſubſequently erect.—Native of mountainous paſtures in many parts of Europe, rare in England, flowering in June and July. The *leaves* are radical, very long, furrowed. *Stalk* round, about three feet high, erect. *Flowers* very numerous, ſmall, greeniſh, by no means ornamental. *Stamens* all of equal length.

O. *nutans*. Drooping Star of Bethlehem. Linn. Sp. Pl. 441. Engl. Bot. t. 1997. Curt. Mag. t. 269. Jacq. Auſtr. t. 301. Fl. Dan. t. 912. Redout. Liliac. t. 253.—Flowers pendulous toward one ſide. Filaments dilated, cohering, bell-ſhaped; three of them longer and cloven.—The original place of growth of *O. nutans* is doubtful; but Dr. Smith thinks it ſo far naturalized in this country as to be admiſſible into the Britiſh catalogue. The ſpecimen figured in Engliſh Botany grew near Bury in Suffolk, where it flowers in great profuſion early in May. *Bulb* large, commonly deep in the ground. *Leaves* all radical, pale, and ſomewhat glaucous, linear, channelled, acute. *Stalk* ſolitary, rather taller than the leaves, cylindrical, erect. *Cluſter* ſimple, a little drooping, compoſed of ſeven or eight large, elegant, greeniſh, ſilvery-white *flowers*, which lean towards one ſide, and as they fade become pendulous.

O. *lacteum*. Large Milk-white Star of Bethlehem. Willd. n. 14. Jacq. Ic. Rar. t. 434. Curt. Mag. t. 1134.—Cluſter long, denſe. Filaments awl-ſhaped, the alternate ones ſlightly dilated. Bracteas membranous, ovate. Leaves lanceolate, acute, fringed.—Native of the Cape of Good Hope, requiring with us the ſhelter of a frame. It blooms in ſummer, and is conſpicuous for its numerous, crowded, large *flowers*, whoſe ovate *petals* are white on both ſides, though greeniſh at the baſe. The *leaves* are about a foot long and an inch broad.

O. *arabicum*. Great-flowered Star of Bethlehem. Linn. Sp. Pl. 441. Herb. Linn. Curt. Mag. t. 728. Redout. Liliac. 63.—Corymb many-flowered. Filaments awl-ſhaped. Corolla widely bell-ſhaped. Outer petals with three ſlight blunt teeth.—Native of Egypt and Madeira, long ſince introduced into our gardens, where it flowers, though very rarely, in the frame in March and April. The *leaves* are numerous, ſpreading, green. *Stalk* above a foot high, bearing an hemiſpherical *corymb* of many very large, fragrant, white *flowers*, furniſhed with a dark-green *germen*.

ORNITHOGALUM, in *Gardening*, contains plants of the bulbous-rooted, flowery, herbaceous, perennial kinds, of which the ſpecies cultivated are: the umbelled ſtar of Bethlehem (O. umbellatum); the yellow ſtar of Bethlehem (O. luteum);

(O. luteum); the ſmall ſtar of Bethlehem (O. minimum); the Pyrenean ſtar of Bethlehem (O. pyrenaicum); the broad-leaved ſtar of Bethlehem (O. latifolium); the pyramidal ſtar of Bethlehem (O. pyramidale); the one-leafed ſtar of Bethlehem (O. unifolium); the Neapolitan ſtar of Bethlehem (O. nutans); the Cape ornithogalum (O capenſe); and the golden ſtar of Bethlehem (O. aureum.)

Method of Culture.—All the ſorts are capable of being increaſed by planting the ſtrong off-ſets from the old roots in the latter end of the ſummer ſeaſon, when their leaves and ſtems begin to decay, either in beds or the borders; the old roots may either be immediately replanted or kept out of the ground ſome time, but they flower much ſtronger when put into the ground in autumn, than if kept out till the ſpring. The ſmall off-ſet bulbs ſhould be planted out in nurſery rows in beds for ſome time, till ſufficiently large to be finally ſet out where they are to grow. They ſhould have a light ſandy ſoil, little manured.

They afterwards require the ſame management as other hardy bulbs, but they ſhould be removed every other year, as when let remain longer they become weak. See BULB.

The two laſt ſorts ſhould have the off-ſets or ſlips planted in ſeparate pots, at the ſame time with the above, filled with good light earth, placing them under a hot-bed frame, ſo as to be protected from wet during the winter ſeaſon, giving them full air in the ſummer. The old roots may be taken up in the autumn as in the other ſorts, and after being kept a little while out of the ground, be replanted in the beginning of the autumn.

The hardy ſorts are all highly ornamental among other flowering bulbous-rooted plants, in the borders, clumps, &c.

And the two laſt kinds afford variety in the collections of potted plants of the flowering bulbous-rooted ſorts.

ORNITHOGLOSSUM, in *Botany*, is ſo denominated from ορνις, *a bird*, and γλωσσα, *a tongue*, on account of the ſhape of the petals. Saliſ. Parad. 54. Ait. Hort. Kew. ed. 2. v. 2. 327. Claſs and order, *Hexandria Trigynia*. Nat. Ord. *Tripetaloideæ*, Linn. *Junci*, Juſſ.

Gen. Ch. *Cal.* none, unleſs the corolla be taken for ſuch. *Cor.* Petals ſix, lanceolate, inferior, ſeſſile, ſpreading, equal, permanent, with a nectariferous depreſſion in the baſe of each. *Stam.* Filaments ſix, inſerted into the receptacle, awl-ſhaped, ſhorter than the corolla, unconnected with it, deciduous; anthers roundiſh-heartſhaped. *Piſt.* Germen ſuperior, roundiſh, furrowed; ſtyles three, divaricated, ſlender, the length of the ſtamens, deciduous; ſtigmas bluntiſh. *Peric.* Capſule ovate, with three furrows, three cells and three valves. *Seeds* ſeveral, ovate, ranged in two rows along the edges of each partition.

Eſſ. Ch. Calyx none. Petals ſix, equal, ſeſſile, permanent. Stamens inſerted into the receptacle, deciduous. Styles deciduous. Capſule of three cells, with many ſeeds.

Obſ. We have already alluded to this genus; ſee the obſervations under the generic character of MELANTHIUM. The only ſpecies known to us is,

1. O. *viride*. Ait. as above. (O. glaucum; Saliſ. Parad. t. 54. Melanthium viride; Thunb. Prodr. 67. Linn. Suppl. 213. Willd. Sp. Pl. v. 2. 269. Andr. Repoſ. t. 233.) —Native of the Cape of Good Hope, from whence it was ſent to Kew by Mr. Maſſon, in 1788. It flowers in the greenhouſe in October or November. *Root* tuberous, perennial, annually proliferous at the ſummit. *Stem* obliquely aſcending, by a taper baſe, under ground, then erect and leafy, two or three inches high. *Leaves* ſheathing, alternate, ſpreading, lanceolate, entire, rather glaucous, ſmooth, hollow, the upper ones ſmall. *Flowers* axillary, ſolitary, on long ſtalks which are tumid at the top. *Petals* dull purple, with a glaucous tinge, channelled. There can be no doubt of Mr. Andrews's ſynonym, though he repreſents the leaves as not glaucous.

ORNITHOGLOSSUM, or *Lingua avis*, has alſo been uſed, by ſome authors, as a name for the ſeed of the aſh.

ORNITHOLOGY, is a word derived from the Greek ορνις, *a bird*, and λογος, *a diſcourſe*, and denotes that branch of natural hiſtory which conſiders and deſcribes birds, their natures and kinds, their form, external and internal, and teaches their economy and uſes. On many of theſe particulars we have treated at large under the word BIRDS, *Anatomy of*; to which we refer the reader, as we do alſo to the ſeveral genera in their alphabetical order. Birds have been defined as two-footed animals, covered with feathers, and furniſhed with wings. Like quadrupeds and the cetaceous tribe, they have warm blood, a heart with two ventricles and two auricles, and lungs for the purpoſe of reſpiration. They are, however, diſtinguiſhed from both by their feet, feathers, wings, and horny bill, as well as by the circumſtance of their females being oviparous.

Hiſtorical View and Claſſification of Ornithology.—Of the hiſtory of this department of ſcience much has been written; we ſhall confine ourſelves to a few particulars. Among the ancients we may notice the writings of Ariſtotle and Pliny. The former compoſed no particular treatiſe on birds, but he refers to them generally in ſeveral parts of his "Hiſtory of Animals." He enumerates the different kinds of nouriſhment adapted to different ſpecies, and their various modes of feeding: he has alſo given an imperfect nomenclature, and remarks on the diverſified modes of nidification, and ſome intereſting obſervations on the family of eagles. Pliny's deſcription of the feathered race is contained chiefly in his tenth book, but it is not at all preciſe, and is mixed with abſurdity and much fabulous matter. Among the more modern ornithologiſts, ſome have directed their labours to method and claſſification: ſome have treated of the whole claſs; others of particular portions of it: ſome have been contented to define and deſcribe, and others have taken vaſt pains to illuſtrate what they have written by deſigns, not always very accurate, from living or prepared ſpecimens. This combination of the effects of the pen, the pencil, and graver, which has ſo eminently contributed, in our day, to the acquiſition and diffuſion of knowledge, ſeems to have been unknown to the ancients.

Among thoſe who firſt excited a taſte, on the continent, for the ſtudy of ornithology, and for a methodical diſtribution of that portion of ſcience, may be mentioned Peter Belon, who flouriſhed in the middle of the 16th century, and who travelled from the laudable deſire of collecting information, which, as we have ſeen in his article, he communicated to the world in various works. (See BELON.) His Hiſtory of Birds, which is a thin volume, divided into ſeven parts, and illuſtrated by wooden cuts, was publiſhed in 1555 at Paris. The principle of claſſification which he adopts, is chiefly founded on the circumſtances of habitation and food, and only occaſionally on external forms and characters: it is accordingly very defective. His deſcriptions are tolerably accurate, but the figures are ſaid to be very inadequate repreſentations of the originals. It is however ſaid, "that he frequently ſuggeſts judicious views of his ſubject; that he notes with ingenuity the points of reſemblance between the human ſkeleton and that of birds, and that he has penned ſeveral paſſages which may be ſtill peruſed with intereſt and inſtruction."

The next perſon in order to be noticed is the celebrated Conrad Geſner, of whom our readers will find a full account in the article already devoted to his labours as a naturaliſt and phyſician. He was a contemporary of Belon, and has aſſigned the third volume of his hiſtory of animals to the department of ornithology. It contains much learning, and exhibits alphabetical tables of the names of birds, in Hebrew, Chaldee, Arabic, Greek, Latin, and moſt of the ſpoken languages. His deſcriptions are chiefly compilations made by abridgments, but his references at the cloſe of each article are numerous, and ſhew that his ſtudies were extenſive, and his knowledge very general. The arrangement of this naturaliſt is that made according to alphabetical order.

The ſame topics are diſcuſſed by Ulyſſes Aldrovandus, or Aldrovandi, a learned phyſician, who, as we have ſeen, vol. i. was denominated the modern Pliny; who availing himſelf of the writings of Belon and Geſner, added greatly to their ſtores, and compiled three folios, divided into twenty books, illuſtrated by wood-cuts. His catalogue compriſes but few birds, excepting ſuch as are natives of Europe. He is ſaid to adopt too implicitly the vague diſtinctions of Belon, to copy too ſervilely from Ariſtotle, and to overſpread his borrowed materials with a maſs of dark commentary. See ALDROVANDI.

Mr. John Johnſton, mentioned in the 19th volume of the New Cyclopædia, publiſhed a thin folio on this ſubject, but he did little more than condenſe the compilations of Geſner and Aldrovandus. In his work he divides the whole claſs of birds into land and water-fowls, and deduces his ſubordinate diviſions from the nature of their aliments. His deſcriptions are well ſpoken of as correct, but ſcanty, and even his figures, though traced with more character than thoſe of his predeceſſors, exhibit much parſimony of engraving.

The next writers of eminence in this branch of zoology were our countrymen Francis Willoughby, or Willughby, eſq. and Mr. Ray. The former laid the foundation of a more accurate arrangement: he obſerved that the hiſtory of animals had in a great meaſure been neglected, and accordingly he made the ſtudy of that his province, and the illuſtration of it his chief and moſt delightful employment. With this view he travelled into foreign countries, with his friends Mr. Ray, ſir Philip Skippon, and other gentlemen, in the year 1663 and 4, on purpoſe to ſearch out and deſcribe the ſeveral ſpecies of animals, beaſts, fiſhes, and inſects. Though he was but a ſhort time abroad, yet he travelled over moſt parts of France, Spain, Italy and Germany, in all which places he was ſo diligent and ſucceſsful, that not many ſorts of animals, deſcribed by others, eſcaped his obſervation. He drew them with a pencil, and afterwards the birds were curiouſly engraved on copper plates, at the charge of his widow, and printed with his ornithology, under the title of "Franciſci Willoughbeii de Middleton, Armigeri, e Reg. Soc. Ornithologiæ Libri tres, in quibus Aves omnes hactenus cognitæ, in Methodum naturis ſuis convenientem redactæ, accurate deſcribuntur: Deſcriptiones iconibus elegantiſſimis et vivarum Avium ſimillimis, æri inciſis, illuſtrantur. Totum opus recognovit, digeſſit, ſupplevit, Joh. Raius." Mr. Ray made conſiderable additions and improvements to Mr. Willoughby's materials, and afterwards tranſlated it into Engliſh, and cauſed it to be printed in 1678. This work of Mr.. Willoughby is divided into three books, which are ſubdivided into chapters. In theſe he treats of the form and external ſtructure of birds, of their organiſation and internal ſtructure. In one part are included twenty-four queries, the anſwers to which, if founded in fact, and drawn up with judgment, would not fail greatly to contribute to the advancement of ornithology. The author recognizes the grand diviſion of terreſtrial and aquatic birds, compriſing under the former thoſe which live at a diſtance from water, and under the ſecond thoſe which live on the margin, or ſurface of that element. He then inſtitutes his leading diſtinction from the form of the bill and feet, and would doubtleſs have accompliſhed a complete arrangement had he uniformly adhered to the ſame principle; but, in compliance with the prejudices of his time, he aſſumes the different kinds of food, the varieties of ſize, the nature of the fleſh, and even what he called the moral qualities, as the grounds of ſubdiviſions. His ſecond and third books contain the deſcription and hiſtory of the ſpecies. To the expoſition of each genus are prefixed general obſervations, including the fabulous accounts of the ancients, and then ſuch common properties as appertain to the genus. The author then proceeds to the ſpecific details, ſtating the moſt important particulars with preciſion, and finiſhes with an account of peculiar habits. Mr. Ray drew up a Synopſis of Birds and Fiſhes, which was publiſhed after his death by Dr. Derham, with the title "Joannis Raii Synopſis methodica Avium et Piſcium; Opus poſthumum, quod vivus recenſuit et perfecit ipſe inſigniſſimus Autor: in quo multas ſpecies, in ipſius Ornithologiâ et Ichthyologiâ deſideratas, adjecit, &c. Iconibus." The figures here referred to are contained in four plates, of which two repreſent Indian birds about Fort St. George, and the others fiſhes diſcovered on the coaſts of Cornwall, by the Rev. George Jago. In the Synopſis the author follows, with a few exceptions, the method of Willoughby, referring at the ſame time to the tail, feathers, and ſome parts of the internal conformation.

Jacob Theodore Klein publiſhed at Lubeck, in 1750, a quarto volume, entitled "Hiſtoriæ Avium Prodromus cum prefatione de ordine animalium in genere." In this work he divides birds into families, orders, and tribes. According to his ſyſtem the eight families are diſtinguiſhed by the conformation of the feet: the orders by the form of the bill: and the tribes ſometimes by the form and proportions of the head, and ſometimes by accidental differences of the bill. Two years after the publication of Klein, we had the ſcientific catalogue of Mœhring, phyſician to the prince of Anhalt. His claſſes, orders, and genera, are founded on the formation of the feet and bill; and his deſcriptions of birds, examined by himſelf, are thought to be very accurate; but for want of a diſcriminating judgment, he is miſled by the errors of others.

Of our great naturaliſt Linnæus we ſhall ſpeak hereafter: to him has been aſſigned the date of 1766, the year in which he publiſhed the 12th edition of his Syſtema Naturæ.

M. Salerne, a phyſician of Orleans, left behind him a manuſcript treatiſe on ornithology, which was publiſhed by his friends. He follows Mr. Ray's method, but the hiſtorical part is from the pen of Salerne. The typography is executed with neatneſs and elegance, and the plates, thirty-one in number, are engraved with uncommon ſkill.

The Syſtem of Ornithology by M. Briſſon, in French and Latin, is compriſed in ſix volumes, quarto. He diſtributes birds into 26 orders, inſtituted from the form of the feet, bill, &c; 115 genera, which are determined by the peculiarities of the bill or mandibles, and about 1300 ſpecies. Each article is preceded by a numerous and accurate liſt of references and figures; many ſpecies, till then undeſcribed, are particularized; and the work is illuſtrated with more than 220 excellent engravings. The principal merit of

Briſſon's plan conſiſts in the adoption of external and permanent characters, which enable the ſtudent to aſſign the name and ſtation of a bird which he ſees for the firſt time. This work is ſaid to be equally accurate with that of Willoughby, and much more copious; and though not free from errors, holds a reſpectable rank in the library of the ornithologiſt.

The Natural Hiſtory of Birds by the Comte de Buffon, and his learned friends, is defective in arrangement, but the ſtyle of the work is popular, luminous, and even elegant, and the plates add greatly to its value. "It poſſeſſes many qualities that recommend it to public attention: it exhibits a clear and comprehenſive view of the knowledge to be acquired in ornithology, ſcattered through a multiplicity of volumes, and in various languages: it diſcuſſes and elucidates, with much critical accuracy, the numerous controverted points: it reduces the whole to ſimplicity, order, and elegance; and by large additions of valuable matter, it greatly extends the bounds of the ſcience." Such is the opinion of the tranſlator reſpecting the value of M. Buffon's Natural Hiſtory. Although the whole work commonly goes under the name of Buffon, yet he derived very important aſſiſtance from his friends. The learned and eloquent M. Gueneau de Montbeillard compoſed the greater part of the two firſt volumes of the Hiſtory of Birds, which appeared, in 1771, under the name of M. de Buffon, and the public did not diſcover the difference of ſtyle which might have been expected in the writings of different authors. It was, however, thought proper to throw off the maſk, and in the ſubſequent volumes each author prefixed his name to his own articles. The third volume was nearly completed when new aſſiſtance was received from the communications of the celebrated Bruce, who on his return from his travels paſſed ſome days with M. de Buffon at Paris. Sonnini's edition of Buffon's Natural Hiſtory contains many valuable additions, and forms, perhaps, one of the moſt complete works of the kind that has yet appeared. In the ornithological department, it gives deſcriptions and figures of every bird to which the editors could have acceſs, either in the living or preſerved ſtate, or of which they could obtain good drawings.

The ornithology of the Encyclopédié Methodique, by M. Mauduyt, is celebrated on account of the preliminary diſcourſes, the accuracy of the deſcriptions and references, and the correct execution of the plates. In the year 1773 Mr. Pennant publiſhed a ſmall volume, entitled "Genera of Birds." In the preface to this work he enters into a minute account of the external parts of birds, their feathers, flight, modification, &c. With reſpect to the ſyſtematic arrangement he gives a decided preference to that of Ray, which he ſays is ſo judicious, that it appears ſcarcely poſſible to make any change in it for the better. In ſpeaking of the Linnæan claſſification, he ſays; "I permit the land-fowl to follow one another, undivided by the water-fowl, the Grallæ and Anſeres of his ſyſtem; but in my generical arrangement, I moſt punctually attend to the order he has given in his ſeveral diviſions, excepting in thoſe of his Anſeres and a few of his Grallæ. For, after the manner of Briſſon, I make a diſtinct order of water-fowl with pinnated feet, placing them between the waders, or cloven-footed water-fowl, and the web-footed. The oſtrich, and land-birds with wings uſeleſs for flight, I place as a diſtinct order. The trumpeter, or Pſophia of Linnæus, and the buſtards, I place at the end of the gallinaceous tribe: all are land-birds; the firſt multiparous, like the generality of the gallinaceous tribe; the laſt granivorous, ſwift runners, avoiders of wet places; and both have bills ſomewhat arched. It muſt be confeſſed, that both have legs naked above the knees; and the laſt, like the waders, lay but few eggs. They ſeem ambiguous birds, that have affinity with each other, and it is hoped that each naturaliſt may be indulged the toleration of placing them as ſuits his own opinion."

In 1781 Mr. Latham commenced his General Synopſis of Birds, a work of much accurate detail, and extending to ſix quarto volumes, with two of ſupplement. He adheres, with few exceptions, to the Linnæan genera, and illuſtrates each genus by one coloured copper-plate engraving, uſual of ſome rare ſpecies. Mr. Latham was likewiſe the author of an "Index Ornithologicus," in two volumes quarto, which forms a convenient appendage to his larger work. The works of this able and induſtrious author conſtitute a precious repoſitory of deſcriptions and facts, and muſt always hold a diſtinguiſhed place in the library of the ornithologiſt. Having ſaid thus much of our own moſt diſtinguiſhed naturaliſts in this department of ſcience, we ſhall give, in a tabular view, their modes of claſſification, that the reader may, with a glance of his eye, almoſt compare them with one another.

In the Linnæan ſyſtem there are ſix orders of birds, *viz.*

- Accipitres.
- Picæ.
- Anſeres.
- Grallæ.
- Gallinæ.
- Paſſeres.

According to Pennant there are nine orders, in two diviſions, which anſwer to the ſix of Linnæus, as in the ſubjoined method.

Diviſion I. Land Birds.	Diviſion I.	Order I. Rapacious	which anſwer to the Linnæan	Accipitres.
		II. Pies		Picæ.
		III. Gallinaceous		Gallinæ,
		IV. Columbine		Paſſeres.
		V. Paſſerine		Paſſeres.
		VI. Struthious		Gallinæ. / Grallæ.
Diviſion II. Water Fowl.	Diviſion II.	VII. Cloven-footed, or Waders		Grallæ.
		VIII. Pinnated-feet		Anſeres. / Grallæ.
		IX. Web-footed		Anſeres. / Grallæ.

TABLE

TABLE of the Orders of Birds according to Mr. Latham.

Ind. Orn.	Syn. of Birds.
Div. I.	Div. I.
I. Accipitres - -	Rapacious.
II. Picæ - - - -	Pies.
III. Paſſeres - -	Paſſerine.
IV. Columbæ - -	Columbine.
V. Gallinæ - - -	Gallinaceous.
VI. Struthiones - -	Struthious.
Div. II.	Div. II.
VII. Grallæ - - -	Waders.
VIII. Pinnatipedes - -	Pinnated-feet.
IX. Palmipedes - -	Web-footed.

For another mode of claſſification we refer our readers to the eighth volume of this work, under the title CLASSIFICATION *of Animals for Comparative Anatomy*. It is not neceſſary in this place to enumerate the genera under their reſpective orders, inaſmuch as they differ but little in the ſeveral ſyſtems. It may, however, be obſerved, that the Lanius, which by Linnæus is placed laſt among the Accipitres, is by Pennant and Latham put firſt among the Picæ: the genera Struthio and Didus, arranged with the order Gallinæ in the Linnæan ſyſtem, make a diſtinct order with Pennant, entitled Struthious; whereas Latham conſiders them only as part of an order, with which he claſſes, as ſeparate genera, the Caſſuarius or caſſowary, and the Rhea, or American oſtrich, which, as will be ſeen hereafter, are but ſpecies of the genus Struthio, in the Linnæan method. Again, Pennant and Latham devote their fourth order to the genus Columba of Linnæus, who conſiders it only one of ſeventeen of the Paſſerine tribe. So that, as is ſeen in the table, the order Paſſeres of Linnæus includes the Columbine and Paſſerine orders of the other naturaliſts, who likewiſe include the Gallinæ of Linnæus in their Gallinaceous and Struthious, and the Grallæ are likewiſe divided among four of their orders, ſome being placed with the Struthious; ſome with the Waders; ſome with thoſe that have Pinnated-feet; and ſome among the Web-footed. The reaſon of theſe changes is obvious: the Swediſh naturaliſt diſtinguiſhes his orders chiefly by the form of the *bill*, but our countrymen ſeparate them from one another according to the characteriſtic form of their feet. It may be farther obſerved, that Pennant makes no diſtinction in his ninth order, the web-footed birds, but Latham divides them into two ſections, *viz.* thoſe with *long*, and thoſe with *ſhort* legs, in the former he places the Recurviroſtra, the Currira, and the Phœnicopterus. Pennant, in his Ornithology, divides all birds into 95 genera, but Latham makes 101, whereas Linnæus includes them all in 90 genera.

Such are the outline of, and diſtinction between, the ſeveral ſyſtems uſually referred to as ſtandards in this country, and which, on that account, we have been particular in explaining.

We may now briefly mention ſome other writers in this branch of ſcience. Francis Hernandez, a Spaniſh phyſician, of whom we have in the proper place given an account, deſcribed the birds of Mexico. His work conſiſts of 229 chapters, each of which generally treats of a ſingle ſpecies. They are deſignated only by their Mexican names, and deſcribed with ſo much brevity, that their preciſe ſtations in the Linnæan arrangement can ſcarcely be aſcertained. The ſame objections apply with equal force to a work of Nieremberg, who has deſcribed the birds of the ſame country. From both, however, it has been inferred, that the feathered tribes in Mexico are numerous, and diverſified with the moſt brilliant colouring. The birds of Brazil preſent a ſtill more rich and ſplendid field for the reſearches of the ornithologiſt, and of theſe a great number have been deſcribed by George Marcgrave, or, as he is deſignated in our 22d vol. MARCGRAF: but whatever he may have been as a delineator of botanical ſubjects, his plates in ornithology are badly executed, and very frequently they do not correſpond with the deſcriptions. See MARCGRAVIA.

Sir Hans Sloane, who was the aſſociate and friend of Boyle and Ray, publiſhed in 1707 the firſt volume of his Hiſtory of Jamaica, but the ſecond did not make its appearance till the year 1725. In this hiſtory he has given repreſentations of 44 ſpecies of birds, but no great reliance can be placed on the accuracy of his delineations.

Mr. Mark Cateſby, of whom we have given a pretty full account in the 7th volume of the Cyclopædia, publiſhed an excellent deſcription of the birds of Carolina, Florida, and the Bahama iſlands, in French and Engliſh: it makes a large portion of "The Natural Hiſtory, &c." referred to in the article already noticed: the firſt volume, and part of the appendix to the ſecond, are devoted to ornithological ſubjects. The deſcriptions are conciſe and perſpicuous, and accompanied with ſome intereſting notices relative to the manners and habits of the ſpecies deſcribed. The plates, which are numerous, are generally faithful repreſentations of the originals, and admirably coloured.

Schwenckfel, who publiſhed his Natural Hiſtory of Siberia in the year 1603, includes birds in his fourth book. The introduction to this work is followed by the enumeration of birds in alphabetical order, according to their Latin names. His deſcription of the parts which belong to birds in common with other animals, and of the appropriate parts of the organization of the former, are neat and accurate, but his differences, founded on habitation and food, are not at all to be depended upon. "The deſcriptions, though accurate, are for the moſt part too ſhort, and though adequate to recall a bird already known, are not ſufficient to convey a preciſe notion of thoſe which are deſcribed for the firſt time."

M. Brunnick, in 1764, publiſhed an account of the birds of Denmark, and the neighbouring iſlands and provinces, but he chiefly dwells on the rare and non-deſcript ſpecies. He generally follows the Linnæan nomenclature, and ſometimes the ſynonymy of Briſſon.

M. Sonnerat publiſhed, in 1776, an account of his voyage to New Guinea, the Molucca, and the Philippine iſlands, the Iſle of France, &c. and in 1783 he gave a narrative of his ſecond voyage to ſeveral parts of the Eaſt Indies and China. This very intelligent traveller exhibits a conſiderable ſhare of accuracy and taſte; and beſides correcting the errors of thoſe who had preceded him, he has noticed a conſiderable number of birds for the firſt time, and moſt of them remarkable for their ſingularity and beauty. His account of the wild cock and hen, the origin of our common domeſtic fowls, is a very intereſting article.

John Leonard Friſch, a German naturaliſt, was, as we have ſeen, author, among many other works, of one entitled, "A Repreſentation of the Birds of Germany, with a few of foreign Countries, coloured after Nature." This work conſiſts chiefly of European birds, arranged in twelve claſſes according to diſtinctions, which are far from preciſe and convenient. In addition to what has been ſaid in the article FRISCH, (which ſee,) may be added, that the figures are, for the moſt part, accurate and lively repreſentations from nature, though, in a few inſtances, they are larger than life. The author has beſtowed uncommon pains on the different colourings of the two ſexes of the ſame ſpecies.

M. le

M. le Vaillant, author of A Voyage to the Cape, and of the "Natural Hiſtory of Birds of Africa," is eminently diſtinguiſhed by the ardour and acuteneſs with which he has proſecuted his ornithological reſearches, and has availed himſelf with laudable diligence of his opportunities of collecting accurate details relative to the ſeveral ſpecies which he undertakes to illuſtrate. His "Natural Hiſtory of the Birds of Paradiſe, Rollers, Toucans, and Barbets," is reckoned the moſt ſplendid publication that has appeared in any of the departments of ornithology. His work is thus deſcribed; "The figures, about 100 in number, are engraved by Pèrèe, from the drawings of Barraband, coloured by Langlois, and retouched by the pencil of the original deſigner; while the elder Didot has executed the typography in his beſt ſtyle, on vellum paper. Each figure is as large as life, and is uſually drawn from a ſpecimen in the higheſt ſtate of preſervation; and in many caſes, an exact repreſentation of the female bird has alſo been obtained. Though the pre-eminent merit of the work conſiſts in the figures and deſcriptions, it is in a few inſtances agreeably diverſified by traits of character which the author remarked in the living bird, and by ſome intereſting hints of a more general complexion, which his accurate and extenſive obſervation enabled him to collect."

M. Anſeline Gaëtan Deſmareſt has given a natural hiſtory of the genera Tanagra, and Pipra of the Paſſerine order: and of the genus Todus in the order Picæ, with coloured plates, from drawings by Paulina de Courcelles, the pupil of Barraband, which reflect great credit on the perſons concerned in ſo ſplendid a work. The paper, type, and figures, all beſpeak the admiration of the reader. The author, Deſmareſt, ſays that they have limited their deſcriptions to ſpecies which they have ſeen, and from which they have been enabled to exhibit figures. Beſides deſcriptions and plates of the male, uſually the moſt beautiful bird, the authors have not unfrequently repreſented the female, or young of the ſame ſpecies, or an individual as it appears in the moulting ſtate.

The natural hiſtory of birds by Mr. George Edwards, in four volumes, 4to., which is without method, and without any reference to particular countries, contains many excellent coloured deſigns, and uſually may be recommended for the correctneſs of the deſcriptions. The ſame obſervation applies to his "Gleanings of Natural Hiſtory," of which the moſt conſiderable portion relates to birds. (See the article EDWARDS, vol. xii.) Several other writers of our own country have deſcribed and delineated the birds of this iſland with various degrees of merit. The ornithological part of Pennant's Britiſh Zoology, has always been regarded as a work of high authority; and ſome others muſt be barely mentioned before we conclude the hiſtorical part of this article, ſuch are Hayes' "Natural Hiſtory of Britiſh Birds," with their portraits accurately drawn and beautifully coloured from nature; Lord's "Natural Hiſtory of Britiſh Birds;" Lewin's "Birds of Great Britain," with delineations of their eggs, in three volumes, 4to.; Walcott's "Synopſis of Britiſh Birds," in two volumes, 4to.; a work on "Britiſh Ornithology," by Mr. Graves; Mr. White's "Natural Hiſtory of Selborne;" and Bewick's "Hiſtory of Britiſh Birds," with figures engraved on wood, in two volumes royal octavo, 1805. The diviſion of the laſt mentioned author is into Britiſh Land and Water Birds, to each of which a volume is devoted. To theſe may be added the Ornithological Dictionary, or Alphabetical Synopſis of Britiſh Birds, by Mr. George Montagu, in two volumes, 8vo. In this work a large portion of accurate and important information is brought within a very narrow compaſs.

External Characters of Birds.—The ſtructure of birds, and their habits of life, are wonderfully adapted to the various functions which they are deſtined to perform. The pointed beak, the long and pliant neck, the expanſive wings, the tapering tail, the light and bony feet, are all wiſely calculated to aſſiſt and accelerate their motion through the yielding air. Every part of their frame is formed for lightneſs and buoyancy; their bodies are covered with a ſoft and delicate plumage, ſo diſpoſed and arranged, as to protect them from the intenſe cold of the atmoſphere through which they paſs; their wings are formed of the lighteſt materials, and yet the force with which they ſtrike the air is ſo great, as to impel their bodies forward with aſtoniſhing rapidity, while the tail ſerves the purpoſe of a rudder to direct them to the different objects of their purſuit. It is not, however, by the power of flying alone, that birds have been diſtinguiſhed from the other claſſes of animals; a ſpecies of ſquirrel, denominated the SCIURUS *volans*, and the bat genus among the MAMMALIA, and the EXOCOETUS *volitans*, (which ſee,) or flying-fiſh, are endowed with the ſame faculty, though in a very imperfect degree. On the other hand, birds of the ſtruthious kind, as the dodo and oſtrich, from their great weight, are wholly unable to aſcend into the regions of the air by means of their wings. Still, however, as we have noticed, birds in their characters differ remarkably from other animals in their external ſtructure, as they do alſo in their internal conformation; if they are deſtitute of teeth, lips, external ears, and ſcrotum; ſo likewiſe they have no epiglottis, no diaphragm, nor urinary bladder. (See BIRD and FEATHER.) As the ſlender ſubſtance of feathers is apt to be diſcompoſed by accident, by illneſs, by terror, or by the exceſſive heat or moiſture of the atmoſphere, nature has made an extraordinary proviſion for their adjuſtment and preſervation in a proper temperament. The animals are furniſhed with a gland behind, which ſecretes a proper quantity of oil, that can be preſſed out by the bird's bill, and laid ſmoothly over the feathers which require to be dreſſed. This gland is ſituated on the rump, and furniſhed with an opening or excretory duct, about which a ſmall tuft of feathers grow, ſomewhat like a painter's pencil. When, therefore, the feathers are rumpled, the bird turning its head backward, with the bill catches hold of the gland, and preſſing it, forces out the oily ſubſtance, with which it anoints the disjointed parts of the feathers, and drawing them out places them in due order. Poultry that live for the moſt part under cover, are not furniſhed with ſo large a ſtock of this fluid as thoſe birds that live in the open air. The feathers of a hen are pervious to every ſhower; but ſwans, geeſe, ducks, and all ſuch as live on the water, have their feathers dreſſed with oil from the firſt day of their leaving the ſhell. Next to the feathers, ſo important to the very exiſtence of birds, we naturally conſider the other parts that have been reckoned deſcriptive of the generic characters of birds. The marks derived from the plumage are precarious indications of the ſpecies to which birds belong; the more important characters of them are all taken by Linnæus from the unfeathered parts; as the beak, caruncles, noſtrils, and feet, and in this principle he has been deſervedly followed by many other naturaliſts. The bill in all birds conſiſts of two mandibles, the upper and the lower; the former is uniformly fixed, except in the genus of parrots, which have the power of moving the upper mandible at pleaſure, to aſſiſt in climbing. No birds have teeth, but ſome have ſerrated mandibles, as the toucans and merganſer, (ſee MERGUS and RAMPHASTOS,) but the ſerræ are not immerſed in ſockets. In the Falco genus, the baſe of the beak or roſtrum is covered with a ſkin called the *cere*, and

in

in the Meleagris, or turkey genus, it is overſpread with a carneous appendage. The noſtrils of birds are generally of an oval form, placed near the baſe of the upper mandible: the organ of ſmell in gannets is ſaid to be wanting, but in moſt birds it is peculiarly acute. The wings of birds in every genus excepting the Struthious, are adapted for flight, which is accompliſhed chiefly by means of the flag-feathers, denominated *remiges*. The largeſt of theſe, named the *primary*, are ſituated on the extremity of the wing, and are generally eight or ten in number; the *ſecondary* are placed nearer the body of the animal; are always ſhorter, and commonly of a different ſhape and colour. There are two ſpecies of the genus Aptenodytes, (ſee PENGUIN,) which are deſtitute of the flag-feathers; with them the wings perform the office of fins, in ſwimming and diving. The larger feathers of the tail have been denominated *rectrices*, from the circumſtance of their being the director or rudder of the animal in flight; for beſides ſerving to counterbalance the fore-parts, they enable the bird to riſe, deſcend, or turn at pleaſure. They ſeldom exceed ten or twelve, except in the Anas genus, in which they are more numerous. See DUCK.

There is a conſiderable difference in the form of their feet, according to their manner of life. Hence the feet have obtained various technical names, as they are fitted for perching, walking, running, ſwimming or diving. For perching, thoſe ſeem beſt adapted which have three toes on the anterior part of the foot, and one backward, with the two outward toes partly connected by a membrane: among walkers this membrane is not to be found. Birds chiefly uſed to ſwimming have their feet wholly palmated, or pinnated, as is the caſe in coots and grebes; or ſemi-palmated, as in the American ſpoon-bill. (See FULICA, COLYMBUS and PLATALEA.) The parrots, woodpeckers, and other genera addicted to climbing, have two toes forwards and two backwards. The oſtrich, the ſwifteſt of all running birds, is in this reſpect anomalous, having only two toes.

Without the means of conveying themſelves with great ſwiftneſs from one place to another, birds could not eaſily ſubſiſt, the food provided for them being ſo irregularly diſtributed, that they are obliged to take long journies to diſtant parts, in order to procure the neceſſary ſupplies. Hence, perhaps, the principal cauſe of thoſe migrations which are ſo peculiar to the feathered race. (See MIGRATION.) It has been ſuppoſed that, during the long flights of birds over immenſe tracts of water, the means of ſubſiſtence would inevitably fail; it ought, however, to be remembered, that this objection is obviated, when we reflect upon the ſuperior velocity with which birds are carried forward in the air, and the eaſe with which they continue their exertions for a much longer time than can be done by the ſtrongeſt quadrupeds. The fleeteſt horſe will ſcarcely run more than a mile in two minutes, and that can be continued for a ſhort time only. In ſuch caſes an uncommon degree of exertion has always been attended with its uſual conſequences, debility, and a total want of power to continue the exertion; but the motions of birds are not impeded by ſimilar cauſes, and they not only glide through the air with a quickneſs ſuperior to that of the ſwifteſt quadrupeds, but can continue on the wing with equal ſpeed for a conſiderable length of time. If we ſuppoſe a bird to go at the rate of a mile in two minutes, and to continue that velocity 24 hours, it will in that time have gone over an extent of 720 miles, or 240 leagues, which is ſufficient to account for the longeſt migration; and if aided by a favourable current of air, there is reaſon to believe, that it will perform the ſame journey in a much ſhorter ſpace of time. For the method by which the flight of birds is performed, ſee the article FLYING. As birds are continually paſſing through hedges and thickets, their eyes are protected from external injuries, as well as from too much light, when flying in oppoſition to the ſun's rays, by a nictitating or winking membrane, which can be drawn over the whole eye like a curtain. This covering is neither opaque, nor wholly pellucid, but ſemi-tranſparent. By means of it the eagle is ſaid to be able to gaze at the ſun.

Of the Nutrition, Neſts, Longevity, Diſeaſes, Fertility, and general Uſes of Birds, in the Economy of Nature.—Birds may be diſtinguiſhed, like the animals of the claſs mammalia, into two kinds, or claſſes, *viz.* the granivorous and carnivorous, and there are ſome that hold a middle nature, and partake of both. Granivorous birds are furniſhed with larger and longer inteſtines than thoſe of the carnivorous kind. Their food, which conſiſts of grain of various ſorts, is conveyed whole and entire into the firſt ſtomach or craw, where it undergoes a partial dilution by a liquor ſecreted from the glands, and ſpread over its ſurface: it is then received into another ſpecies of ſtomach, where it is farther diluted; after which it is tranſmitted into the gizzard, or true ſtomach, conſiſting of two very ſtrong muſcles, covered externally with a tendinous ſubſtance, and lined with a thick membrane of prodigious power and ſtrength; in this place the food is completely triturated, and rendered fit for the operation of the gaſtric juices. (See BIRDS, *Anatomy of*.) Granivorous birds partake much of the nature and diſpoſition of herbivorous quadrupeds. In both, the number of their ſtomachs, the length and capacity of their inteſtines, and the quality of their food, are very ſimilar; they are likewiſe diſtinguiſhed by the gentleneſs of their temper and manners. Their chief attention is directed to procuring food, hatching and rearing their offſpring, and avoiding the ſnares of men, and the attacks of birds of prey, and other rapacious animals. They are in general ſo tractable as eaſily to be domeſticated. Carnivorous birds are diſtinguiſhed by the powers with which they are furniſhed by nature for the purpoſe of procuring their food. They are provided with wings of great length, the muſcles which move them being proportionably large and ſtrong, whereby they are enabled to keep long upon the wing in ſearch of prey: they are armed with ſtrong hooked bills, and ſharp and formidable claws: their ſight is ſo piercing and acute, as to enable them to view their prey from the greateſt heights in the air, upon which they dart with inconceivable ſwiftneſs, and undeviating aim: their ſtomachs are ſmaller than thoſe of the granivorous kinds, and their inteſtines are much ſhorter. The analogy between the ſtructure of rapacious birds and carnivorous quadrupeds is very obvious: both of them are provided with weapons which indicate deſtruction and rapine; their manners are fierce and unſocial, and they ſeldom live together in flocks, like the granivorous tribes. When not on the wing, rapacious birds retire to the tops of ſequeſtered rocks, or to the depths of extenſive foreſts, where they conceal themſelves in ſolitude. Thoſe which feed on carrion are endowed with a ſenſe of ſmelling ſo exquiſite, as to enable them to ſcent putrid carcaſes at aſtoniſhing diſtances.

Moſt birds, at certain ſeaſons, live together in pairs, and the union generally continues while the united efforts of both are neceſſary in forming temporary habitations, and in rearing their offspring. Eagles and other birds of prey continue their attachment for a much longer time, and ſometimes for life. The neſts of birds are conſtructed with ſo much art as to baffle the utmoſt exertion of human ingenuity to imitate them. The mode of building, the materials they make uſe of, as well as the ſituations they ſelect, are as various as the different kinds of birds, and are all admirably adapted to their ſeveral wants and neceſſities. Birds of the ſame ſpe-

cies

cies collect the ſame materials, arrange them in the ſame manner, and make choice of ſimilar ſituations for fixing the places of their temporary abodes. Wherever they diſpoſe themſelves, they always take care to be accommodated with a ſhelter, and if a natural one does not offer itſelf, they very ingeniouſly make a covering of a double row of leaves, down the ſlope of which the rain trickles, without entering into the little opening of the neſt that lies concealed below. In forming the neſt, they make uſe of dry wood, bark, thorns, reeds, thick hay, and compact moſs, as a foundation, and on this, as a firſt layer, they ſpread and fold in a round form all the moſt delicate materials, as down, wool, ſilk, ſpiders' webs, feathers, and other light ſubſtances, adapted for the purpoſes for which they are intended, and to the climate in which the neſts are ſituated. Thus, the oſtrich in Senegal, where the heat is exceſſive, neglects her eggs during the day, but ſits on them in the night. At the Cape of Good Hope, where the heat is leſs, the oſtrich, like other birds, ſits upon her eggs both day and night. In countries infeſted with monkies, many birds, which in other climates build in buſhes and clefts of trees, ſuſpend their neſts upon ſlender twigs, and thus elude the utmoſt art of their enemies. In all caſes we may obſerve, without entering into particulars, that the architecture of the neſts of each ſpecies ſeems to be adapted to the number of eggs, the temperature of the climate, or the reſpective dimenſions of the little animal's body. Small birds, whoſe eggs are generally numerous, make their neſts warm, that the animal heat may be equally diffuſed, but the larger ſpecies are leſs ſolicitous in this reſpect. The ſmaller tribes alſo, that live upon fruit and corn, and are often regarded as unwelcome intruders upon the labours of man, uſe every caution to conceal their neſts from the eye, while the only ſolicitude of the great bird is to render their refuge inacceſſible to wild beaſts and vermin.

As ſoon as the important buſineſs of neſt-making is completed, the female lays her eggs, the number of which varies according to the ſpecies: ſome have only two at a time, others four, five, or more, up to eighteen. (See the article EGG.) When the eggs are laid, the male and female brood over them by turns, though this is generally the province of the female.

The term of life varies greatly in birds, and does not ſeem to bear the ſame proportion to the time of acquiring their growth, as has been remarked with regard to quadrupeds. Moſt birds acquire their full dimenſions in a few months, and are capable of propagation the firſt ſummer after they are hatched. In proportion to the ſize of their bodies, they poſſeſs more vitality, and live longer than either man or quadrupeds. It is no very eaſy taſk to aſcertain the ages of birds; nevertheleſs we have, on unqueſtionable authority, inſtances of great longevity in many of them, particularly geeſe, ſwans, ravens, and eagles; among which, eagles have been known to attain the age of ſixty, ſeventy, eighty, or even a hundred years. The following ſcale has been given by Linnæus, Buffon, and other celebrated naturaliſts:

An eagle will live	100 years.
A raven -	100
A gooſe - -	70
A partridge -	25
A turtle-dove -	25
A peacock - -	25
A pigeon from 10 to	20

Linnets, goldfinches, canary-birds, and others in a ſtate of captivity, have been known to live many years. The longevity of birds has been imputed to the texture of their bones, the hardneſs and ſolidity of which have been aſſigned as the general cauſe of death in other animals. Thoſe of birds being lighter, and more porous in their conformation, preſent fewer obſtacles to the vital powers. Hence it has been aſſumed that the leſs ſolid the bones are, the more diſtant will be the period of death.

From the great longevity of birds, it has been inferred that they are ſubject to a few diſeaſes only: their annual moulting is thought to be the only one to which they are univerſally liable. As quadrupeds caſt their hair, ſo all birds every year obtain a new covering of feathers: this is what is termed moulting. During its continuance, they always appear ſickly and diſordered; the boldeſt loſe their courage; none produce young, and many die under the ſevere viſitation. No feeding can maintain their ſtrength, or preſerve their powers of reproduction. The nouriſhment which formerly went to the production of young, is now conſumed and abſorbed in adminiſtering a ſupply to the growing plumage. The manner in which nature performs this operation is ſlow in its progreſs. When birds have attained their full ſize, the pen part neareſt the animal grows harder and thicker in its ſides, but ſhrinks in its diameter: in conſequence of the firſt of theſe proceſſes, it draws gradually leſs nouriſhment from the body of the animal; and by its decreaſe in ſize, it becomes looſe, till it at length falls off. In the mean time, the rudiments of an incipient quill are forming; the ſkin becomes in ſhape like a little bag, which is fed from the body by a ſmall vein and artery, and which every day increaſes in ſize, till it is protruded. While one end vegetates into the beard or vane of the feather, that part attached to the ſkin is ſtill ſoft, and receives a conſtant ſupply of nouriſhment, which is diffuſed through the body of the quill by the artery and vein. When, however, the quill is come to its full growth, and requires no farther nouriſhment, the vein and artery become gradually leſs, till at laſt the ſmall opening by which they communicated with the quill is ſtopped, and the circulation ceaſes. The quill, after it is thus deprived of new ſupplies, continues for ſome months in the ſocket, till at laſt it ſhrinks, and makes room for another repetition of the ſame proceſs of nature. The moulting ſeaſon commences at the end of ſummer, and the bird continues to ſtruggle under the malady for a conſiderable part of the winter: then the appetite of the animal is leaſt craving, while its proviſions continue to be moſt ſcanty. It is not till the return of ſpring, when the feathers have attained their full growth, that the abundance of food and the mildneſs of the ſeaſon reſtore it to its full vigour.

A few words on the uſes of birds to the world, and its inhabitants, ſhall conclude this article. The rapacious kinds evidently ſerve the purpoſe of preſerving the ſalubrity of the air, by devouring all ſorts of carrion, ſcattered over the ſurface of the earth. The natural death, or accidental deſtruction of living creatures would communicate to the atmoſphere a putrid and noxious influence, were their carcaſes allowed to diſſolve and mingle with the ſoil by the ſlow proceſs of corruption. The order Grallæ co-operate in this employment. They deſtroy toads, lizards, ſerpents, &c. which would otherwiſe increaſe too faſt; and devour their bodies, that would more or leſs infect the air with putrid vapours. Hence the inhabitants of Holland and of Egypt are indebted to the labours of the ſtork. In the latter country, which abounds with every hideous reptile that a humid ſoil or ſultry ſun can quicken into life, this favourite bird is protected, even in its wild ſtate, by the laws of the land. The granivorous birds are alſo deemed of great utility in the ſyſtem of nature, inaſmuch as they abridge the fertility of thoſe weeds, which emit ſuch immenſe quantities

of ſeed, as would ſoon overſpread the earth, and which, if left unreſtrained, would infallibly overpower the more uſeful vegetables. Many ſpecies are uſeful in tranſporting ſeeds from one country to another, and thus diſſeminate plants more univerſally over the ſurface of the globe. Beſides the uſes to which the feathered tribes are ſubſervient in the general plan of nature, we may contemplate their connection with man, and obſerve how far they contribute to his pleaſure and advantage. It is worthy of obſervation, that of the vaſt number of birds which inhabit the globe, it has never been diſcovered that a ſingle one is of a poiſonous nature. They differ very much in being more or leſs ſalutary and palatable, as an article of diet; but none of them are pernicious. None of their eggs have been found to poſſeſs any noxious qualities; a circumſtance well known to ſeafaring people and travellers, who eat freely, and without the ſmalleſt heſitation, every ſpecies of egg, without finding any inconvenience from them.

As an article of food, all carnivorous birds are avoided, though not poiſonous: the piſcivorous alſo, eſpecially thoſe with ſharp bills, are generally diſliked, though ſome of the young are eaten with avidity. All water-fowl are generally reckoned a heavy and rancid food: the gooſe and duck are probably the beſt, and theſe are greatly improved by being fed on grain, and by being reſtricted, as much as poſſible, from fiſhes, ſlugs, worms, &c. Birds that live almoſt wholly on inſects are likewiſe generally avoided as an article of food; while the ſmaller birds, that ſubſiſt upon grain or ſeeds, are very much eſteemed. The woodcock, the ſnipe, and bittern, the whole tribe called mud-ſuckers, are accounted a great delicacy.

It has been remarked as a matter of ſurpriſe, that ſo few birds have been ſubſervient to economical uſes by domeſtication. They are naturally ſhy and timid, and appear but little ſuſceptible of attachment and obedience. Jealous of liberty, and furniſhed with effectual means of eſcape, they fly the haunts of men, and by far the greater part continues in the primitive wildneſs of nature. Few, even of thoſe that we denominate domeſtic, diſcover that familiarity or affection that obtains among thoſe quadrupeds which have given up independence for protection. Of the rapacious birds, not one ſpecies has ever been domeſticated by man, excepting for the purpoſes of falconry; and theſe are always taken, when young, from the neſts of the wild ones, a proof that they do not thrive and propagate in their captivity. The order Picæ, likewiſe, contains not one ſpecies that has ever been reduced to a domeſtic ſtate; but in the order Gallinæ, we have ſeveral ſpecies which have, with great advantage, been made ſubſervient to the purpoſes of domeſtic economy: ſuch are the peacock, turkey, the barn-door fowl, and the Guinea hen. Of the columbine tribe, one ſpecies only has been tamed, *viz.* that of the common pigeon. None of the paſſerine or ſtruthious orders have ever been domeſticated, though many of the former are reckoned delicate food. Four ſpecies of the duck kind have been brought from their wild ſtate to the ſervice of man; the ſwan, gooſe, Guinea duck, and the wild duck. The Grallæ, though excellent food, have none of them been domeſticated; ſo that it has been obſerved, that of four thouſand different ſpecies deſcribed by Latham, not more than ten or twelve have been rendered ſerviceable to the human race.

ORNITHOMANCY, a kind of divination, or method of arriving at the knowledge of futurity by means of birds.

Ornithomancy, amongſt the Greeks, was the ſame with augury among the Romans. See Augury and Omen.

ORNITHOPARCHUS, Andreas, in *Biography*, was born at Meinungen: he was maſter of arts, and author of the moſt general and extenſive treatiſe on practical muſic, that was produced in Germany after the writings of Gaffurio had appeared. His treatiſe was called Micrologus in imitation of Guido, and publiſhed at Cologn in 1535, though Walther thinks that was not the firſt edition. The author chiefly cites John Tinctor, Franchinus, and the tract written by our countryman John Cotton, whom he calls pope John XXII. His treatiſe, though the beſt of the time, ſeems too meagre and ſuccinct to have been of great uſe to the ſtudents of ſuch muſic as was then practiſed. It was, however, tranſlated into Engliſh in 1609, ſeventy years after its firſt publication, by our countryman John Douland, the celebrated luteniſt; a labour which he might have well ſpared himſelf, as Morley's Introduction, which was ſo much more full and ſatisfactory, precluded all want of ſuch a work as that of Ornithoparchus.

ORNITHOPUS, in *Botany*, a name altered by Linnæus from the *Ornithopodium* of preceding botaniſts, and derived, like that, from ὄρνις, *a bird*, and πούς, *a foot*, the legumes having a ſtriking reſemblance to the toes of many ſmall birds. Linn. Gen. 381. Schreb. 503. Willd. Sp. Pl. v. 3. 1155. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 776. Prodr. Fl. Græc. Sibth. v. 2. 79. Juſſ. 361. Lamarck Illuſtr. t. 631. Gærtn. t. 155. (Ornithopodium; Tourn. t. 224.)—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, with five nearly equal marginal teeth, permanent. *Cor.* papilionaceous. Standard inverſely heart-ſhaped, entire. Wings ovate, ſtraight, ſcarcely ſo large as the ſtandard. Keel minute, compreſſed. *Stam.* Filaments diadelphous, (one ſimple, the other in nine diviſions); anthers ſimple. *Piſt.* Germen linear; ſtyle briſtle-ſhaped, aſcending; ſtigma a terminal point. *Peric.* Legume awl-ſhaped, round, curved, jointed, with intermediate partitions, the joints falling off ſeparately. *Seeds* ſolitary, roundiſh.

Eſſ. Ch. Legume jointed, round, curved.

1. O. *perpuſillus*. Common Bird's-foot. Linn. Sp. Pl. 1049. Curt. Lond. faſc. 6. t. 53. Engl. Bot. t. 369. Fl. Dan. t. 730. (Ornithopodium minus; Ger. em. 1241.)—Leaves pinnate. Flowers capitate, accompanied by a leaf. Legumes incurved, beaded.—Native of ſandy or gravelly paſtures in various parts of Europe. A moſt elegant little annual plant, flowering in May. The *root* is fibrous, but often bears little fleſhy tubercles by which it is propagated, and in that caſe it cannot ſtrictly be termed annual. *Stems* proſtrate, much branched, from three to twelve inches long, furrowed, downy. *Leaves* pinnate, of numerous pairs of equal, elliptical, hairy, rather fleſhy leaflets, with an odd one at the end. *Flowers* in ſmall heads, on axillary ſtalks, with a leaf, of fewer leaflets than the others, at the ſummit of each common ſtalk, cloſe to the flowers. The *ſtandard* and *wings* are white, the former prettily ſtreaked with crimſon; *keel* greeniſh. *Legumes* parallel, beadlike, ſlightly compreſſed, pointed, downy, containing one ſeed in each of the numerous joints. There is a more luxuriant variety, whoſe floral leaf, as well as the flowers, are much larger than in our Britiſh kind. This is *Ornithopodium majus*, Ger. em. 1241.

2. O. *compreſſus*. Compreſſed Yellow Bird's-foot. Linn. Sp. Pl. 1049. Sm. Fl. Græc. Sibth. t. 714, unpubliſhed. (Scorpioides leguminoſa; Ger. em. 1241.)—Leaves pinnate. Flowers capitate, accompanied by a leaf. Legumes compreſſed, even-jointed, rugged, recurved.—Native of Italy, Sicily, and Greece, ſometimes raiſed for curioſity in our gardens, where it is a hardy annual, flowering about June. Larger than the former, with which it much agrees

in general habit, but the *corolla* is entirely yellow, and the *legumes* very different, being recurved, much flattened, and formed of quadrangular closely united joints, making the outline of the margin even, scarcely at all beaded, or notched.

3. O. *durus*. Spiral Bird's-foot. Cavan. Ic. v 1. 31. t. 41. f. 2. Willd. n. 3.—Leaves pinnate. Flowers capitate, naked. Legumes spirally recurved, nearly cylindrical, with slightly curved joints.—Native of hills in Spain, flowering in May and June. *Root* annual, not perennial. *Stems* erect, rigid, branched, three or four inches high. *Leaflets* usually but three or four pair, with an odd one, obtuse, thick, smooth, and glaucous. *Flowers* deep yellow, two or three on each stalk, unaccompanied by a leaf. *Legumes* spiral, slender, their joints somewhat lunate as in *Hippocrepis*.

4. O. *scorpioides*. Purslane-leaved Bird's-foot. Linn. Sp. Pl. 1049. Cavan. Ic. v. 1. 26. t. 37.—Leaves ternate, nearly sessile; the odd leaflet very large.—Differs from all the former in the great size of its terminal *leaflets*, and the round kidney-shape of the only pair of lateral ones. The *flowers* are yellow. *Legumes* most like those of the last species. The whole of the herbage is glaucous and rather succulent. No *leaf* accompanies the *flowers*.

5. O. *tetraphyllus*. Four-leaved Bird's-foot. Linn. Amœn. Acad. v. 5. 402. Sp. Pl. 1049. (Quadrifolium erectum, flore luteo; Sloane Jam. v. 1. 186. t. 116. f. 3.)—Leaves quaternate. Flowers solitary. Legume beaded.—Native of meadows in Jamaica, on a clay soil. This has the habit of a *Lotus*. The *leaflets* are obovate, emarginate, slightly downy, besprinkled with glandular dots, and grow four together at the summit of a short common *footstalk*. *Flowers* yellow, solitary, on axillary stalks, with a pair of *bracteas*. *Legume* incurved, slightly beaded, covered with resinous dots, its numerous joints tumid, and obliquely obovate. Linnæus suspected this plant might form a new genus, for which we see no other reason than its foliage; but that indeed is foreign to the nature of the other species, and in this tribe is undoubtedly very important.

6. O. *lævigatus*. Smooth Bird's-foot.—Leaves pinnate. Flowers somewhat capitate, naked. Legumes incurved, cylindrical, with obsolete joints.—Native of Europe. Gathered by the abbé Durand at Gibraltar. We have it from Jacquin's herbarium for *O. perpusillus*, with which many botanists seem to have confounded it, yet the plants are totally distinct. The present is much larger than the *perpusillus*, with narrower more distant *leaflets*, and only one or two *flowers* on a stalk, without any floral leaf. *Corolla* yellow. *Legume* much incurved, slender, nearly cylindrical, so even that the joints are hardly discernible; its surface minutely reticulated, without hairs or downiness.—It seems wonderful that authors should have overlooked this species, which was certainly unknown to Linnæus. The *Ornithopodium pusillum*, Dalech. Hist. v. 1. 487, seems intended for it, and is indeed a very good representation, the second, or smaller figure in his p. 486, being unquestionably the real *perpusillus*. The figure we have above cited for the latter in Ger. em. appears taken from Dalechamp's p. 487, but the legumes are some of them made more jointed, and the description certainly belongs to *perpusillus*, as indeed does the account in Dalechamp, p. 487. The first *Ornithopodium* of this author appears to be *Ornithopus compressus*.

ORNITHOSCOPI, ορνιθοσκοποι, in *Antiquity*, diviners, or soothsayers, who made predictions, and drew omens, from birds. They were likewise called *ornithomantes*, and *orneoscopi*, &c.

ORNITROPHE, in *Botany*, so called by Commerson, from ορνις, *a bird*, and τροφη, *food*, because the fruit is a favourite food of blackbirds in the isle of Bourbon, whence the French inhabitants have named the first species of this genus Bois de Merle. Juss. 247. Lamarck Illustr. t. 309. Willd. Sp. Pl. v. 2. 322. Ait. Hort. Kew. v. 2. 348.—Class and order, *Octandria Monogynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four deep, ovate, rather unequal segments. *Cor.* Petals four, roundish, with a beard or crest in the centre of their disk. *Stam.* Filaments eight, inserted into a glandular receptacle, thread-shaped, the length of the corolla; anthers roundish. *Pist.* Germen stalked, two-lobed, compressed; style one, divided; stigmas simple. *Peric.* Drupas two, ovate, small, slightly pulpy, each of one cell; one of them sometimes abortive. *Seed.* Nut solitary, obovate.

Ess. Ch. Calyx in four deep segments. Petals four. Style cloven. Germen two-lobed. Drupas two.

1. O *integrifolia* Entire-leaved Ornitrophe. Willd. n. 1. Lamarck fig. 1.—Leaves ternate, ovato-lanceolate, wavy, nearly entire.—Gathered by Commerson in the island of Bourbon. A *shrub*, with round, smooth, knotty branches. *Leaves* alternate, on longish stalks, ternate; *leaflets* stalked, two or three inches long, nearly equal, elliptic-oblong, bluntly pointed, unequally and slightly wavy, smooth, veiny. *Stipulas* none. *Clusters* axillary, stalked, solitary, very minutely downy, their branches very short, and each bearing a tuft of small greenish *flowers*, on smooth partial stalks. One lobe of the *germen* being usually abortive, the fruit becomes a solitary pear-shaped *drupa*, the size of a pea

2. O. *serrata*. Saw-leaved Ornitrophe Ait. n. 1. Roxb. Coromand. v. 1. 44. t. 61.—Leaves ternate, rough, ovate, pointed, serrated.—One of the most common plants on the coast of Coromandel. Dr. Roxburgh observes that among the mountains it grows to a small tree, but in the low lands near the sea it is a low branching shrub, flowering during the wet season. The natives call it *Tauatiky*, and eat the fruit, which is small and red, growing in pairs, both lobes of the *germen* coming to perfection. The habit is much like the last, but the *leaflets* are strongly serrated, and the *petals* turned all to one side, which does not appear to be the case in that, as far as we can learn from figures or dried specimens. Some *flowers* want the pistil.

3. O. *Cobbe*. Ceylon Ornitrophe. Willd. n. 3. (Rhus Cobbe; Linn. Sp. Pl. 382 Kobbæ; Herm. Zeyl. 24. Linn. Zeyl. 205.)—"Leaves ternate, ovate, acute, serrated, downy beneath. Stalk of the clusters downy."—Native of Ceylon. We have seen neither specimen nor figure. Linnæus says the *leaves* are either ternate or quinate. His description of the *inflorescence* accords with both the preceding, but the common stalk seems to be more downy. The fruit is said to be black.

4. O. *Cominia*. Yellow-berried Ornitrophe. Willd. n. 4. (Rhus Cominia; Linn. Sp. Pl. 381. Schmidelia Cominia; Swartz Ind. Occ. v. 2. 667. Baccifera indica trifolia, fructu rotundo monopyreno; Sloane Jam. v. 2. 100. t. 208. f. 1.)—Leaves ternate, elliptic-oblong, unequally serrated, downy beneath. Common flower-stalks branched, downy.—Native of Jamaica; cultivated by Miller in 1759. A *tree* thirty feet high. *Leaves* dark green above; white and downy, with innumerable reticulated veins, beneath. *Flowers* very small, thickly set in dense hairy clusters, several of which grow on one branched downy common stalk. The *fruit* is described by Sloane as no bigger than a small pin's head, orange-coloured, with very little pulp. *Molago Maram*, Rheede Hort. Malab. v. 5. 49. t. 25, quoted for this species by Linnæus, has whitish *fruit*, and more distant *flowers*,

flowers, otherwiſe they ſeem nearly allied; but we have reaſon to think there are many ſpecies of this genus as yet undeſcribed by ſyſtematic writers; nor is our knowledge at preſent ſufficient for us to ſettle the ſynonyms of thoſe already publiſhed.

5. O. *occidentalis*. Weſt-Indian Ornitrophe. Willd. n. 5. (Schmidelia occidentalis; Swartz Ind. Occ. v. 2. 665. Alophyllus racemoſus; Swartz Prodr. 62.)—Leaves ternate, ſlightly downy beneath. Cluſters ſolitary.—Native of buſhy hills in Hiſpaniola.—A *ſhrub*, nine or ten feet high, with many ſmooth branches. *Leaflets* nearly ſeſſile, cloſe together, oblong, contracted at the lower part, pointed, ſlightly downy beneath; the lateral ones oblique at the baſe. *Cluſters* ſimple. *Flowers* white, ſmall; on ſome ſhrubs male only.

6. O. *rigida*. Rigid Simple-leaved Ornitrophe. Willd. n. 6. (Schmidelia rigida; Swartz Ind. Occ. v. 2. 663. Alophyllus rigidus; Sw. Prodr. 62.)—Leaves ſimple, with ſpinous teeth. Cluſters ſolitary. Native of dry mountainous parts of Hiſpaniola, but extremely rare. A rigid *ſhrub*, with alternate, ſimple, ſtalked, lanceolate *leaves*, rough above, downy beneath, with ſtrong reticulated veins, and ſmall ſpinous marginal teeth. *Cluſters* axillary, ſolitary, ſtalked, hairy.

After all that has been ſaid of this genus, it is perhaps not diſtinct from *Schmidelia*, with which it preciſely accords in habit, differing chiefly in having but one *ſtyle*, inſtead of two, and a *calyx* with four deep ſegments, inſtead of one of two leaves. But the twin *germen* in *Ornitrophe*, ſhews the former character to be but ambiguous, and the *calyx* having two larger and two ſmaller ſegments, renders the latter ſomewhat ſuſpicious. See SCHMIDELIA.

ORNON, in *Geography*, an iſland in the Baltic, near the coaſt of Sweden. N. lat. 68°. E. long. 18° 6′.

ORNOS, a ſea-port on the S. coaſt of the iſland of Myconi. N. lat. 37° 24′. E. long. 25° 20′.

ORNUS, in *Botany*, the name of a plant mentioned by Virgil and Pliny; as a large and majeſtic tree, preferring mountainous ſituations. It is generally taken for the Manna Aſh, or μελια of Dioſcorides; ſee FRAXINUS *Ornus*. Geſner, Ruellius, Dodonæus, and ſome others, have ſuppoſed our Mountain Aſh, *Pyrus ancuparia*, Fl. Brit. to be the true *Ornus*. Dodonæus very rightly obſerves that Virgil in his Georgics, book 2. l. 71, ſpeaks of it as a tree on which the pear was engrafted. This is much in favour of his opinion, though he did not deduce any argument from it. The pear is much more likely to ſucceed by grafting on a ſtock of its own natural order or genus, than on one ſo remotely allied as any *Fraxinus*. Virgil moreover always ſpeaks of the majeſtic growth and ſtrength of his *Ornus*, which is far more applicable to the plant of Dodonæus, Ruellius, and Geſner than to the Manna Aſh.

ORO, in *Geography*, a mountain of Switzerland, in the country of the Griſons; 13 miles W. of Bormio.

ORO, *Cape d'*, the eaſtern point of the iſland of Negropont, anciently called "Caphareus," in the iſland of Eubœa. N. lat. 38° 8′. E. long. 24° 40′.—Alſo, a cape on the W. coaſt of Africa, called "Oleredo." N. lat. 23° 30′. W. long. 15° 20′.

OROBANCHE, in *Botany*, Ορoβαγχη of the Greeks, ſo called from ορoβος, *a vetch*, and αγχω, *to ſtrangle* or *ſuffocate*, becauſe this paraſite is believed to ſtarve, or render barren, the plants on which it grows. Having been originally obſerved upon the Broom in England, it is here named Broom-rape. Linn. Gen. 321. Schreb. 421. Willd. Sp. P. v. 3. 347. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 668. Prodr. Fl. Græc. Sibth. v. 1. 440. Juſſ. 101. Tourn. t. 81. Lamarck Illuſtr. t. 551. Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of two leaves moſtly divided, lateral, ſometimes combined at their baſe, erect, coloured, permanent. *Cor.* of one petal, ringent, withering. Tube bending, ample, inflated. Limb ſpreading; its upper lip concave, dilated, notched; lower reflexed, three-cleft, uneven at the margin, its ſegments various in ſize and proportion. Nectary a gland, in front, at the baſe of the germen. *Stam.* Filaments four, awl-ſhaped, concealed under the upper lip, two of them longeſt; anthers erect, approximated, ſhorter than the corolla, tumid, two-lobed and acutely awned. *Piſt.* Germen ſuperior, oblong; ſtyle ſimple, the length and poſition of the ſtamens; ſtigma drooping, thick, of two obtuſe lobes. *Peric.* Capſule ovate-oblong, pointed, of one cell and two valves. *Seeds* numerous, minute. *Receptacles* four, linear, lateral, attached to the valves.

Eſſ. Ch. Calyx of two lateral leaves. Corolla ringent. Capſule of one cell and two valves. Seeds numerous. A gland under the germen in front.

* *Bracteas ſolitary.*

1. O. *major*. Greater Broom-rape. Linn. Sp. Pl. 882. Sutton Tr. of Linn. Soc. v. 4. 175. Engl. Bot. t. 421. Curt. Lond. faſc. 4. t. 44.—Stem ſimple. Corolla inflated; the ſegments of its lower lip equal and acute. Stamens ſmooth. Style downy.—Native of Europe, in buſhy places on a barren ſandy ſoil, growing paraſitically on the roots of *Spartium* or *Ulex*, and flowering in June and July. The *root* is ſuppoſed to be perennial, and fixes itſelf by numerous fleſhy fibres. Whole *herb* of a dull purpliſh-brown, the *corolla* only when freſh being rather more purple than the reſt. The *ſtem* is ſimple, erect, angular, downy, ſucculent, about a foot high, clothed with ſcattered, lanceolate, leafy *ſcales*, ſhorter and more crowded about the bottom, which aſſumes a ſwelling ovate figure. *Spike* terminal, ſimple, rather cloſe, of many *flowers*, each of which is accompanied by a ſimple lanceolate *bractea*. *Calyx* of two lateral oppoſite leaves, each divided more than half way down into two equal, lanceolate, acute ſegments. *Corolla* an inch long, inflated, a little incurved, keeled at the back; its upper lip entire, with a reflexed waved margin; lower in three equal, acute, dependent lobes, more or leſs wavy or ſlightly crenate; theſe are beſt repreſented in the diſſection of the flower in Engl. Bot. and in every part of Curtis's figure. *Stamens* channelled and quite ſmooth in their lower part, though a little glandular at the very ſummit. *Style* downy throughout, with a ſmooth *ſtigma* of two yellow ſeparate little globes. Every author has confounded this ſpecies with *O. major garyophyllum olens* of Bauhin's Pinax, 87, till the writer of the preſent article diſtinguiſhed them; ſee the next ſpecies. Even Ray fell into this error, the true plant of Bauhin not being a native of Britain; and Curtis attributes to ours "a faint ſmell of cloves," which it has not, from reading in various books that ſuch a ſcent belonged to *O. major*.

2. O. *caryophyllacea*. Clove-ſcented Broom-rape. Sm. Tr. of Linn. Soc. v. 4. 169. Willd. n. 3. (O. major; Pollich. Palatin. v. 2. 200. O. n. 295; Hall. Hiſt. v. 1. 129. O. major, garyophyllum olens; Bauh. Pin. 87.)—Stem ſimple. Corolla inflated, criſped at the edge; the ſegments of its lower lip equal and obtuſe. Lower part of the ſtamens hairy on the inner ſide. Native of Germany, Switzerland, and Italy. Our ſpecimens were gathered in April 1787, on ſhrubby hills near Valcimara, at the foot of the Apennines. This has the appearance of the former, but ſmells ſtrongly like cloves,

when freſh. It has, moreover, the three ſegments of the lower *lip* obtuſe, and much more fringed and curled. The *germen* is entirely ſmooth, which in *O. major* is hairy in the upper part, and the *ſtyle* is much leſs downy than in that ſpecies. But the ſtrongeſt mark of diſtinction is found in the copious hairs which clothe the inner ſide of the *ſtamens*, that part being always quite ſmooth in the *major*. The *ſtigma* is brown or purpliſh, that of the *major* yellow. We have received Swiſs ſpecimens which prove this to be Haller's n. 295. That author deſcribes a variety with a denſe conical ſpike, a very ſhort *flower*, and very prominent *ſtyle*, of which he had ſeen a drawing only. Linnæus had a ſpecimen from Pomerania, which anſwers exactly to this deſcription, and appears really to be a variety of our *caryophyllacea*, with which its *ſtamens* and *ſtigma* exactly agree. We have from Dr. Roth an Hercynian ſpecimen, marked *O. arenaria* of Borkhauſen, which is likewiſe our *caryophyllacea*.

3. O. *fœtida*. Fœtid Broom-rape. Desfont. Atlant. v. 2. 59. t. 144. Willd. n. 2. (O. major *β*; Vahl. Symb. v. 2. 70. O. flore ſpecioſo fimbriato ruberrimo; Shaw Spec. n. 452.)—Stem ſimple. Corolla ſomewhat inflated; all its ſegments rounded, and toothed at the edge. Stamens hairy at the top and bottom. Style ſlightly hairy upwards.—Frequent in wild as well as cultivated ground in Barbary, in the ſpring. We have a ſpecimen from M. Desfontaines. It is taller and more ſlender in habit than either of the former, with a long cylindrical ſpike. The *calyx-leaves* are ſplit into two deep, long, and narrow, unequal ſegments. *Corolla* dark purple; its upper lip in two, and lower in three, all nearly equal rounded lobes, ſharply toothed at the edge. *Stamens* hairy at the very baſe and ſummit only, otherwiſe ſmooth. *Style*, and top of the *germen*, beſprinkled with hairs. The *flowers* are ſaid to be fœtid, but, according to Vahl, this circumſtance is variable.

4. O. *rubra*. Red Fragrant Broom-rape. Sm. Engl. Bot. t. 1786.—Stem ſimple. Corolla tubular, fringed; its upper lip cloven; lower in three nearly equal ſegments. Stamens fringed on one ſide at the baſe; germen and ſtyle at their ſummits. Calyx-leaves undivided.—Diſcovered by John Templeton, eſq. a moſt acute and obſerving botaniſt, growing plentifully on the baſaltic rock at Cave-hill, near Belfaſt, in Auguſt 1805. The *roots* creep, but do not appear to be attached to thoſe of any other plant. Whole plant near a foot high, of a purpliſh-red, ſlightly downy. The *flowers* ſmell powerfully like a honeyſuckle or pink. It ſeems moſt akin to the laſt, but the ſegments of the upper *lip* are conſiderably larger than thoſe of the lower; all of them are minutely fringed with fine glandular hairs. The peculiar lateral pubeſcence of the *germen*, *ſtyle*, and *ſtamens*, in the parts above-mentioned, and, above all, the undivided *calyx-leaves*, diſtinguiſh this ſpecies from all the foregoing.

5. O. *cæruleſcens*. Blueiſh Broom-rape. Willd. n. 4.—Stem ſimple. Corolla tubular. Bracteas the length of the flower, clothed, like the divided calyx-leaves, with white hairs. Stamens and ſtyle ſmooth.—Native of Siberia, near the Caſpian ſea, from whence it was ſent to Profeſſor Willdenow by his friend Stephanus. We have a ſpecimen, gathered at Algiers by the late M. Brouſſonet, which anſwers in every point to Willdenow's deſcription, except that the *ſtyle* and *germen* in ours are glandular. He deſcribes his plant as having a ſimple *ſtem*, near a foot high, ſtriated, downy, clothed above with white ſhaggy hairs, as are alſo its *ſcales* or *leaves*. *Spike* denſe, three inches long, white in conſequence of the long ſnowy hairs which cover the *bracteas* and *calyx*, though the *flowers* are blueiſh. *Bracteas* ovate, with a taper point equal to the flowers. *Calyx-leaves* in two deep, unequal, awl-ſhaped ſegments, almoſt as long as the tube of the *corolla*, which is not inflated. *Stamens* and *piſtil* ſmooth.

6. O. *comoſa*. Tufted Broom-rape.—Stem ſimple. Corolla inflated. Bracteas hairy; the lower ones broad and ovate; the upper elongated and taper-pointed. Stamens and ſtyle ſmooth. We have received this from our learned friend Mr. Schmaltz of Palermo, by the name of *O. rubra*; but it is different from what we have deſcribed above under that appellation, the *calyx-leaves* being deeply divided. The *ſcales* of the ſtem, as well as the lower *bracteas*, are remarkably broad, obtuſe, and covered externally with white ſhaggy hairs; while the upper *bracteas* are furniſhed with long, ſpreading, ſmooth points, and crowded into a tuft, apparently producing no flowers. The inflated *corolla* ſeems to diſtinguiſh it from the laſt; the lower *lip* is in three very obtuſe, broad lobes, connected by elevated plaits.

7. O. *elatior*. Tall Broom-rape. Sutton Tr. of Linn. Soc. v. 4 178. t. 17. Sm. Fl. Brit. n. 2. Engl. Bot. t. 568. Willd. n. 5. (O. major; Sibth. Oxon. 191, according to Profeſſor Williams.)—Stem ſimple. Corolla tubular; the ſegments of its lower lip equal and acute. Stamens downy. Style ſmooth.—Common in fields, and about their borders, in England and Germany, eſpecially on a gravelly ſoil, flowering in July and Auguſt. This is taller, and of a more yellowiſh hue than *O. major*, with which moſt botaniſts have confounded it, but the Rev. Dr. Sutton, by attending to the hairineſs of the *ſtamens*, firſt well diſtinguiſhed the preſent ſpecies. Its *roots* moſtly adhere to thoſe of *Trifolium pratenſe*, or *Centaurea Scabioſa*. The *flowers* are more copious than in any other Britiſh ſpecies, with a leſs turgid *corolla*, whoſe upper lip is divided, dilated, fringed, and criſped. They have no ſcent. The *calyx-leaves* are united in front. Upper part of the *ſtamens*, as well as the whole *ſtyle* and *germen*, very ſmooth. *Stigma* inverſely heart-ſhaped, yellow.

8. O. *minor*. Leſſer Broom-rape. Sm. Fl. Brit. n. 3. Engl. Bot. t. 422. Sutton Tr. of Linn. Soc. v. 4. 179. Willd. n. 7. (O. major; Loefl. Hiſp. 151. O. flore minore; Bauh. Hiſt. v. 2. 781. Dill. in Raii Syn. *288. Tourn. Inſt. 176.)—Stem ſimple. Corolla tubular; the middle ſegment of its lower lip lobed. Stamens fringed. Style ſmooth.—Abundant in fields of clover in Britain, on whoſe roots it grows paraſitically. Loefling gathered it on the roots of elms, in the royal gardens of Aranjuez, and his ſpecimens are in the Linnæan herbarium. This is ſmaller than the laſt, with fewer and ſmaller *flowers*, whoſe *calyx-leaves* are diſtinct, and variable in ſhape, being ſometimes undivided. The *ſtamens* are merely fringed at their edges. *Stigma* dilated, purple. The middle ſegment of the *lip* being larger, and moſtly three-lobed, is a ſtrong character. The colour of the whole plant is uſually purpliſh, but there is a variety with pale yellow *flowers*, reſembling the *Monotropa* in hue.

9. O. *alba*. White Broom-rape. Willd. n. 8.—Stem ſimple. Corolla tubular, toothed; its lower lip in three rounded, nearly equal ſegments. Stamens ſlightly fringed below. Style hairy upwards. Calyx-leaves undivided, combined.—Native of Siberia, near the Caſpian ſea. *Stem* half a foot high, tawny and hairy. *Spike* about two inches long, the lower *flowers* remote. *Bracteas* ovate, acute, hairy, rather exceeding the *calyx*, whoſe ſegments are undivided, combined at their baſe. *Corolla* cylindrical, the ſize of the laſt, white, clothed with glandular hairs. Upper *lip* inverſely heart-ſhaped, toothed; lower as above deſcribed. *Filaments* ſmooth, dilated at the baſe, where they

are

are furniſhed with a few glandular marginal hairs. *Germen* ſmooth. *Style* ſmooth, clothed with glandular hairs in the upper part. *Stigma* large, two-lobed. *Willd.* We have ſeen no ſpecimen.

10. O. *gracilis*. Slender-ſtalked Broom-rape. Sm. Tr. of Linn Soc. v. 4. 172. Willd. n. 9.—Stem ſimple. Corolla inflated; its lower lip very ſhort, the ſegments inverſely heart-ſhaped, unequal, criſped and jagged. Stamens and ſtyle looſely hairy, prominent.—Gathered by the writer of this, in July 1787, in hilly paſtures at St. Orſeſe near Genoa. Dr. Noehden found the ſame high on the Pyrenées. This is of a more ſlender habit than any of the above, and is from one to two feet high. The large inflated *corolla*, and ſhort lower *lip*, eſſentially diſtinguiſh it from *O. minor*, as well as the hairy *ſtyle*, and greater length of the *ſtamens*. We do not recollect the plant's having when freſh any peculiar ſmell.

11. O. *cernua*. Drooping-flowered Broom-rape. Linn. Sp. Pl. 882. Loeſl. Hiſp. 152, excluding the ſynonyms.—Stem ſimple. Corolla tubular, bent downward; its upper lip divided; lower in three equal rounded ſegments, flat. Stamens ſlightly fringed at the baſe. Style ſmooth, incurved.—Gathered by Loefling, whoſe ſpecimen is before us, on the roots of *Artemiſia campeſtris*, in very barren fields at Aranjuez in Spain. *Stem* about ſix inches high. *Spike* lax, of about a dozen ſmooth pale *flowers*, with a purple limb, remarkable for the ſtrong curvature in their tube, by which the mouth is turned directly downwards. The *bracteas* are broad, ovate, ribbed and downy. *Calyx-leaves* ovate, inflated; thoſe of the lower flowers entire, of the upper uſually cloven. *Stamens* and *ſtyle* ſtrongly incurved. Can this be the *O. media*, Desfont. Atlant. v. 2. 59?

12. O. *americana*. American Broom-rape. Linn. Mant. 88. Willd. n. 10.—Stem ſimple. Scales imbricated, ſmooth, Corolla tubular, bent downward; its upper lip vaulted; lower in three equal oblong ſegments. Stamens and ſtyle incurved, very ſmooth. Calyx ſimple.—Sent by the late Dr. Garden, from South Carolina. The whole plant is remarkably ſmooth, yellow, a ſpan high. *Scales* cloſely imbricated, poliſhed, pale, ovate. *Spike* denſe, of numerous *flowers*, ſmaller than any of the foregoing, and deflexed as in the laſt. *Bracteas* lanceolate, pale and ſmooth like the ſcales of the ſtem. *Calyx* of one leaf, ſcarcely divided.

13. O. *virginiana*. Virginian Broom-rape. Linn. Sp. Pl. 882. Willd. n 11. (O. minor virginiana lignoſior, per totum caulem floribus minoribus onuſta; Moriſ. v. 3. 502. ſect. 12. t. 16. f. 9.)—Stem branched. Corolla tubular; its lower lip in three equal acute ſegments. Calyx ſimple, four-toothed. Capſule globoſe.—Gathered by Banniſter and Kalm in Virginia. This is widely different from all the foregoing, in its ſlender much-branched *ſtem*, and ſmall, racemoſe, numerous, rather diſtant *flowers*. The *bracteas* are ſmall and ovate, about as long as each partial *flower-ſtalk*. *Calyx* hemiſpherical, with four teeth. *Corolla* ſlender, ſomewhat incurved, about half an inch long; its *lips* ſmall, the upper vaulted. *Style* prominent, with a capitate, ſcarcely lobed *ſtigma*. The *ſtamens* we have no opportunity of examining.

14. O. *purpurea*. Purple Cape Broom-rape. Linn. Suppl. 288. Willd. n. 6.—Stem ſimple, racemoſe. Corolla tubular; its limb in four rounded equal ſegments. Calyx ſimple, five-cleft. Anthers curved, with a double ſpur at their baſe.—Gathered at the Cape of Good Hope by Thunberg. This appears to us very improperly referred to the genus in queſtion, with which its *calyx* and *corolla* by no means agree. We have not ſufficient materials to fix it firmly elſewhere. The plant is a foot high, nearly leafleſs, downy, purple, turning black in drying. *Corolla* an inch and a half long, curved, taper at the baſe. *Flower-ſtalks* about as long as the *corolla*, with an oblong *bractea* at the baſe of each.

* * *Bracteas three together.*

15. O. *cærulea*. Purple European Broom-rape. Villars Dauph. v. 2. 406. Sm. Fl. Brit. n. 4. Engl. Bot. t. 423. Sutton Tr. of Linn. Soc. v. 4. 182. Willd. n. 13. (O. purpurea; Jacq. Auſtr. t. 276. O. Gmel. Sib. v. 3. t. 46. f. 1. O. n. 294; Hall. Hiſt. v. 1. 129. O. quarta; Lob. Ic. v. 2. 269. O. ſecunda; Cluſ. Hiſt. v. 1. 271. O. flore majore; Ger. em. 1312.)—Stem ſimple. Bracteas ternate. Upper lip of the corolla divided and notched.—Native of graſſy paſtures near the ſea, at Montpellier, as well as in Hampſhire and Norfolk. It is alſo found in Auſtria, Siberia, and Switzerland. This ſpecies flowers with us in July. It is rare, and its ſynonyms have been very much miſunderſtood. Linnæus, who did not know the plant, confounded its hiſtory with that of a Siberian *Lathræa*, under the name of *O. lævis*, which appellation it was impoſſible to retain for the preſent plant, and therefore the above was choſen. The habit is more ſlender, and leſs pubeſcent, than any of our three Britiſh ſpecies in the firſt ſection, the colour more dark and violet; the *flowers* longer. The *bracteas* are three, one large and external, two ſmaller, internal. *Calyx* tubular at the baſe, the leaves being united; their lobes in two nearly equal awl-ſhaped ſegments. *Corolla* paliſh violet, ribbed, tubular much longer than the bracteas; its upper lip aſcending, more or leſs deeply two-lobed, with a notch or two between the lobes; lower of three equal, ovate, entire, dependent lobes, not undulated, the palate elevated, divided, white and downy. *Stamens* entirely ſmooth. *Germen* ſmooth; *ſtyle* a little downy. The *Orobanche* of Beſl. Hort. Eyſt. æſt. ord. 7. t. 2, cited by Bauhin under his *O. flore majore*, (ſee Tr. of Linn. Soc. v. 4. 167.) appears intended for the ſpecies before us, though bad, and perhaps imitated from old wooden cuts. It is ſcarcely poſſible that this or any *Orobanche* ſhould have been cultivated in the garden at Aichſtat, though it might grow in the neighbouring fields. The hiſtory of the confuſion between this plant and the *Orchis abortiva* of Linnæus, which gave riſe to the report of the latter growing in Hampſhire, is given at length by the writer of the preſent article, in Tr. of Linn. Soc. v. 4. 164. The reader may alſo conſult Sm. Fl. Brit. 927.

16. O. *ramoſa*. Branched Broom-rape. Linn. Sp. Pl. 882. Sm. Fl. Brit. n. 5. Engl. Bot. t. 184. Sutton Tr. of Linn. Soc. v. 4. 185. Willd. n. 17. Ger. em. 1312. (O. n. 296; Hall. Hiſt. v. 1. 130. O. Camer. Epit. 311.)—Stem branched. Bracteas ternate. Upper lip of the corolla in two rounded entire ſegments. This grows amongſt Hemp, to which plant its roots are attached, and whoſe ſeeds it is ſuppoſed to render abortive. It occurs in various parts of Europe, flowering in the latter part of ſummer. This is more nearly allied to the laſt, and to *O. cernua*, than any other. With *cæruleæ* it agrees in having a pair of internal *bracteas*, but the *ſtem*, being invariably more or leſs branched, except occaſionally perhaps in a very poor ſtarved ſpecimen, diſtinguiſhes it from all except the *virginiana*, and with that it has few characters in common beſides. The *ramoſa* is of a brighter purple hue in its *flowers* than any other Britiſh *Orobanche*, and in Greece the colour is ſtill more vivid, and the plant very beautiful as well as luxuriant. The ſegments of the *corolla* are more equal and rounded than in *cærulea*, nor are there any intermediate teeth or

notches in the upper lip. The *root* of the ſpecimen figured in Engl. Bot. is diſeaſed and ſwollen, in conſequence of the attacks of ſome inſect, probably a *Cynips*.

*** *Bracteas none.*

17. O. *uniflora.* Single-flowered Broom-rape. Linn. Sp. Pl. 882. Willd. n. 12. (Gentianella minor aurea, flore ſingulari amplo deflexo pallidé flaveſcente; Pluk. Mant. 89. Phyt. t. 348. f. 3.)—Stems ſingle-flowered. Calyx without any bractea.—Native of Maryland and Virginia. The *root* is ſmooth, ſomewhat creeping, branched, thick, but ſhort, furniſhed with rounded alternate *ſcales*, and perhaps ought to be reckoned a partly ſubterraneous ſtem. From within each of the ſcales ſprings a ſolitary, erect, round, ſimple, naked *ſtem* or *ſtalk*, four or five inches high, rather downy, eſpecially upward, bearing one large rather drooping *flower*, of the ſame yellowiſh or purpliſh hue as in ſeveral of the other ſpecies. The *calyx* is bell-ſhaped at the baſe, the leaves being united; but whether there are four ſegments or five, our ſpecimens are not in a condition to ſhew. *Corolla* above an inch long, ribbed, downy; its upper lip in two deep, rounded, obtuſe lobes; lower in three ſimilar equal lobes; all finely fringed with glandular hairs. *Stamens* and *ſtyle* much ſhorter than the corolla, all ſmooth, at leaſt in their upper half. Plukenet's figure repreſents the *corolla* as with only four ſegments; hence Willdenow refers this ſpecies to his firſt ſection; but his mode of ſubdividing the genus is very exceptionable.

Willdenow unites with this genus the *Phelypæa* of Tournefort and Desfontaines, which we cannot but conſider as well diſtinguiſhed by the five deep rounded ſegments of its *calyx*, to ſay nothing of the habit. See PHELYPÆA.

Æginetia, publiſhed by Linnæus in the firſt edition of Sp. Pl. but referred to *Orobanche* in the ſecond, is well reſtored by Dryander in Roxb. Coromand. v. 1. 63. t. 91, and by Willdenow, Sp. Pl. v. 3. 347. Its *calyx* is of one leaf, burſting laterally, and the *capſule* of numerous cells.

OROBOIDES, a name given by Hippocrates, and other authors, to a furfuraceous ſediment in the urine of perſons who have the jaundice: it is uſually of a reddiſh-brown colour; and is not peculiar to that diſeaſe, but is found in ſome others.

OROBUS, in *Botany*, a name borrowed from the Greeks, whoſe ὀροβος, however, is generally ſuppoſed to be the *Ervum*, or Tare, of the Latins, a very different genus from what we now call *Orobus*. Ambroſinus derives the word from ὀρω, *to excite*, and βους, *an ox*, becauſe horned cattle, feeding upon this plant, thrive, and grow courageous, or prone to combat. Linn. Gen. 374. Schreb. 496. Willd. Sp. Pl. v. 3. 1072. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 761. Prodr. Fl. Græc. Sibth. v. 2. 63. Juſſ. 360. Tourn. t. 214. Lamarck Illuſtr. t. 633. Gærtn. t. 151. —Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, obtuſe at the baſe; its orifice oblique, with five very ſhort teeth; the three lowermoſt ſharpeſt; the two uppermoſt ſhorteſt, moſt deeply and obtuſely divided; withering. *Cor.* papilionaceous. Standard inverſely heart-ſhaped, reflexed at the ſummit and ſides, longer than the other petals. Wings two, oblong, nearly equal to the ſtandard, aſcending, cohering together. Keel manifeſtly divided below, pointed, aſcending; its margins parallel, cohering, compreſſed; tumid in front. *Stam.* Filaments in two ſets, one ſimple, the other in nine diviſions, curved upwards; anthers roundiſh. *Piſt.* Germen cylindrical, compreſſed; ſtyle thread-ſhaped, bent upwards, erect; ſtigma linear, downy at the inner ſide from the middle to the top of the ſtyle. *Peric.* Legume round, long, with a ſharp aſcending point, of one cell and two valves. *Seeds* numerous, roundiſh.

Eſſ. Ch. Style linear, roundiſh, downy above. Calyx obtuſe at the baſe; its two upper ſegments deepeſt and ſhorteſt.

1. O. *lathyroides.* Upright Blue Bitter-vetch. Linn. Sp. Pl. 1027. (Lathyroides erecta, &c.; Amman. Ruth. 114. t. 7. f. 2.)—Leaves in pairs, elliptical, nearly ſeſſile. Stipulas toothed.—Frequent throughout Siberia in open mountainous graſſy paſtures, flowering in June and July. Sibthorp gathered it on mount Athos. Miller is ſaid to have cultivated it formerly. We ſaw the plant in flower at Meſſrs. Lee and Kennedy's in 1809, but it is of rare occurrence in gardens, though worthy of notice on account of its beautiful tufts, or ſhort cluſters, of blue *flowers*, which partake of the elegance of form, and variegation of colour, proper to this genus. The *root* is perennial. *Stems* upright, ſimple, leafy, a foot and half high. *Leaves* alternate, of two light-green, elliptical, more or leſs blunt, entire, ſmooth leaflets, above an inch long, reticulated with copious veins, nearly ſeſſile, with a minute briſtle between them. *Stipulas* broadiſh, half-arrowſhaped, variouſly toothed. *Flower-ſtalks* axillary, ſolitary, ſhorter than the leaves, bearing a cluſter of eight or ten inodorous *flowers*, all turned one way. The *calyx* is purpliſh, ſlightly hairy. *Claws* of all the *petals* pale. Summit of the *keel* and *wings* of a beautiful blue, with darker veins. *Seeds* four or five, in a long narrow *legume*, with ſpiral valves.

2. O. *hirſutus* Hairy Bitter-vetch. Linn. Sp. Pl. 1027. Sm. Fl. Græc. Sibth. t. 690, unpubliſhed. (O. ſylvaticus, foliis circa caulem auriculatis; Buxb. Cent. 3. 22. t. 41.) —Leaves in pairs, ovate, ſtalked. Stipulas entire, nearly as big as the leaflets.—Native of ſhady woods in Thrace, flowering in May; *Buxbaum*. Sibthorp gathered it on Parnaſſus, Hæmus, and the Sphaciotic mountains of Crete. The *ſtems* are much taller than in the laſt, and branched, but weak and trailing. *Leaflets* not half ſo large, acute, with parallel veins, fringed at the edges, and ſupported by a common *ſtalk* near an inch long, at whoſe baſe ſtands a pair of large *ſtipulas*, much like the leaflets, but elongated into an acute point at the baſe. Common *flower-ſtalks* three or four times as long as the leaves, hairy, each bearing but two or three rather large pea-like *bloſſoms*, whoſe *calyx* is hairy, with long taper teeth, the *ſtandard* of a light violet blue, the *wings* paler, and *keel* nearly white. This ſpecies has not as yet been ſeen in our gardens.

3. O. *luteus.* Yellow Bitter-vetch. Linn. Sp. Pl. 1028. (O. montanus; Scop. Carn. v. 2. 60. t. 41. O. n. 17; Gmel. Sib. v. 4. 13. t. 4. O. n. 419; Hall. Helvet. v. 1. 182. O. pannonicus quartus; Cluſ. Pann. 741. Hiſt. v. 2. 231. O. montanus, flore albo; Ger. em. 1248. Galega montana; Dalech. Hiſt. 1139.)—Leaves pinnate, with about five pair of elliptic-lanceolate leaflets. Stipulas half-arrowſhaped, toothed.—Native of the Alps and Pyrenées, as well as of mountains in Hungary, and about rivers in Siberia, flowering in May. Dr. Sibthorp gathered it on the Bithynian Olympus. We have ſeen it cultivated by the preſent Biſhop of Carliſle at Ealing, and occaſionally elſewhere, nor can we help regretting that ſo fine a plant, which Haller ſays is one of the moſt handſome of the papilionaceous tribe, and with whoſe figure and deſcription in Cluſius and his followers he juſtly finds fault, has not appeared in our periodical works, inſtead of uſeleſs repetitions of well-known ſpecies, or trifling varieties. The *root* is certainly perennial, not annual. *Stems* annual, numerous, two or three feet high, ſometimes ſimple, but moſtly branched, leafy, angular.

Leaves

Leaves of four or five pair of elliptic-lanceolate briſtle-pointed leaflets, glaucous beneath, an inch and half long, with a ſmall linear-lanceolate terminal briſtle, or abortive leaflet. *Flower-ſtalks* longer than the leaves, each bearing from ſix to ten large drooping *flowers*, tinged with various ſhades of pale yellow and buff-colour. Cluſius calls them white, and the root annual. The figure in Dalechamp is better than his, but Gmelin's is the beſt. Miller's t. 193. f. 1. deſcribes the flowers as purple.

4. O. *vernus*. Spring Bitter-vetch. Linn. Sp. Pl. 1028. Curt. Mag. t. 521. (O. venetus; Cluſ. Hiſt. v. 2. 232. Ger. em. 1247.)—Leaves pinnate, with about three pair of ovate taper-pointed leaflets. Stipulas half-arrowſhaped, entire. Stem ſimple.—Native of mountainous woods, chiefly in the northern parts of Europe, though Dr. Sibthorp gathered it on mount Athos and the Bithynian Olympus. With us it is only a garden plant, but a very pretty one, conſpicuous in April or May for its broad bright-green *leaves*, and copious ſhowy *flowers*, variegated with crimſon and blue. A little ſhelter ſecures its beauty in the fickle ſpring of our climate.

5. O. *tuberoſus*. Common Bitter-vetch, or Heath Pea. Linn. Sp. Pl. 1028. Sm. Fl. Brit. n. 1. Engl. Bot. t. 1153. Curt. Lond. faſc. 1. t. 53. Fl. Dan. t. 781. (Aſtragalus ſylvaticus; Ger. em. 1237.)—Leaves pinnate, with about three pair of elliptic-lanceolate leaflets, ſtipulas half-arrowſhaped, toothed at the baſe. Stem winged.—Native of paſtures, woods and thickets, on a ſtrong ſoil, in the north of Europe more eſpecially. The *roots* are knobbed and perennial, much eſteemed by the Scottiſh Highlanders, for their ſweet taſte and nutritious qualities. The *herb* is about a foot high, with dark-green *leaflets*, which vary in breadth, and are ſometimes found quite linear. The *flowers* are racemoſe, large and handſome, with a browniſh and glaucous *calyx*, a ſtandard elegantly varied with purple, crimſon and blue, and pale wings.

6. O. *albus*. White Auſtrian Bitter-vetch. Linn. Suppl. 327. Willd. n. 6. (O. pannonicus; Jacq. Auſtr. t. 39.)—Leaves pinnate, with two pair of linear leaflets. Stipulas half-haſtate, lanceolate, entire. Stem without wings.—Native of Auſtria and Hungary. The *root* is perennial, furniſhed with many cylindrical knobs. *Stem* ſimple or branched, a foot or two high, angular, without wings. *Leaflets* two inches long and about a line wide, two pair on each common ſtalk. *Stipulas* lanceolate, entire, each with a ſmall horizontal lobe at the baſe. *Cluſters* on long ſtalks of about four white *flowers*, the ſize of the laſt. *Legume* compreſſed.

7. O. *anguſtifolius*. Siberian Narrow-leaved Bitter-vetch. Linn. Sp. Pl. 1028. Gmel. Sib. v. 4. 14. t. 5.—Leaves pinnate, with two pair of linear ſword-ſhaped leaflets. Stipulas half-haſtate, awl-ſhaped, entire. Stem unbranched, without wings.—Native of Siberia. The *root* is unknown. *Stem* ſimple. *Leaflets* remarkably narrow, ſlightly hairy. *Stipulas* of two awl-ſhaped long lobes, one erect, the other horizontal. *Flowers* racemoſe, yellow in the Linnæan wild ſpecimen from Siberia, but Gmelin deſcribes them as purple. His figure is careleſsly drawn, and we ſuſpect he may have confounded with this plant the narrow-leaved variety of *O. tuberoſus*, as many others have done.

8. O. *ſeſſilifolius*. Oriental Seſſile-leaved Bitter-vetch. Sm. Prodr. Fl. Græc. Sibth. v. 2. 64. Fl. Græc. t. 692, unpubliſhed. (O. orientalis, foliis anguſtiſſimis, coſtæ breviſſimæ innaſcentibus; Tourn. Cor. 26.)—Leaves in pairs, ſword-ſhaped, nearly ſeſſile. Stipulas awl-ſhaped. Stems numerous, unbranched.—Gathered by Dr. Sibthorp about Athens and Meſſena. *Root* perennial, tapering, branched. *Stems* many, weak, unbranched, angular, without wings. *Leaves* of only one pair of narrow, dark-green, nearly ſeſſile *leaflets*. *Stipulas* very narrow, entire, half-arrowſhaped. *Flowers* dark-purple, about four in each cluſter.

9. O. *caneſcens*. Grey French Bitter-vetch. Linn. Suppl. 327. Willd. n. 8. (Arachi vel apios leguminoſæ ſpecies, Toſſano Carolo; Bauh. Hiſt. v. 2. 326. cap. 21.)—Stem branched. Leaves pinnate, with two pair of linear-lanceolate leaflets. Stipulas half-arrowſhaped, awl-ſhaped.—Native of Burgundy. *Bauhin*. We know this merely from the authors cited, not having ſeen any ſpecimen. It is ſaid to differ from *O. anguſtifolius*, in having a branched *ſtem*, and whitiſh-blue *flowers*. The figure and deſcription of Bauhin anſwer very nearly to the narrow-leaved variety of the *tuberoſus*.

10. O. *varius*. Parti-coloured Bitter-vetch. Soland. MSS. Curt. Mag. t. 675. (O. anguſtifolius italicus, flore vario; Tourn. Inſt. 393. Aſtragalus quibuſdam, aracho Toſſani Caroli ſimilis; Bauh. Hiſt. v. 2. 326. cap. 22.)—Leaves pinnate, with about four pair of linear-lanceolate leaflets. Stipulas half-arrowſhaped, entire. Stem winged, branched above.—Native of Italy, near Bologna. A hardy perennial with us, eaſily propagated by offſets from the roots, and flowering abundantly in May or June, when its parti-coloured and very elegant bloſſoms are a great ornament to the parterre. Linnæus ſeems to have confounded this in his herbarium with *anguſtifolius*, from which it totally differs in its winged and branched *ſtem*, much broader and more numerous *leaflets*, and broader *ſtipulas*. The *flowers* are about ſix in each cluſter; their *calyx* red; *ſtandard* crimſon, fading to a pale yellow; *wings* and *keel* variegated with yellow and buff. Curtis ſays it rarely produces ſeed in England.

11. O. *atropurpureus*. Dark-purple Bitter-vetch. Deſfont. Atlant. v. 2. 157. t. 196. Willd. n. 9.—Leaves pinnate, with about three pair of linear leaflets. Stipulas half-haſtate, ſomewhat toothed. Stem roundiſh, ſtriated. Flowers tubular.—Gathered by Desfontaines in neglected fields at Algiers. We have a Sicilian ſpecimen from Mr. Bivona Bernardi, which that excellent botaniſt was inclined to think a diſtinct ſpecies, becauſe the *ſtems* are more angular than Desfontaines repreſents. The *root* is perennial, rather woody. *Stems* twelve or eighteen inches high, roundiſh, but with ſome appearance of angles, ſtriated, either ſimple or branched. *Leaves* of two or three pair of linear, very narrow leaflets, on a common ſtalk an inch long. *Flowers* from four to twelve or more, in a denſe cluſter, turned one way, on a long ſtalk. *Corolla* about an inch in length, the pale claws of its *petals* remarkably long, cohering in a tubular manner, their limb deep purple or violet.

12. O. *niger*. Black Bitter-vetch. Linn. Sp. Pl. 1028. Willd. n. 10. (O. ſylvaticus, viciæ foliis; Riv. Tetrap. Irr. t. 60. Aſtragaloides; Ger. em. 1239.)—Stem branched. Leaves pinnate, with about ſix pair of ovate-oblong ſmooth leaflets.—Native of various parts of Europe, from Sweden to Greece, but not of Britain. We have long had it in curious gardens, flowering about June. The *ſtem* is erect, branched, two or three feet high, angular. *Leaves* copious, of about ſix pair of ovate, bluntiſh, awned, ſmooth leaflets, paler beneath, an inch long, on a common ſtalk tipped with a briſtle. *Cluſters* ſhortiſh, of from four to ſix dull purple *flowers*, their common ſtalk longer than the leaves. The whole plant turns black in drying.

13. O. *pyrenaicus*. Pyrenæan Bitter-vetch. Linn. Sp. Pl. 1029. Scop. Carn. v. 2. 59. O. pyrenaicus latifolius nervoſus; Pluk. Phyt. t. 210. f. 2.)—Stem branched. Leaves pinnate, with two pair of elliptical ribbed leaflets.

Stipulas

Stipulas ſomewhat ſpinous.—Native of the Pyrenées, and of Carniola. We have ſeen no ſpecimen. The *root* is marked as perennial. The *ſtem* is ſaid by Scopoli to be angular, and in ſome degree winged. *Leaflets* ovate-oblong, with ſlightly hairy ribs beneath. *Flowers* racemoſe, pendulous. *Standard* red, marked with darker lines. *Legume* ſlightly downy.

14. O. *ſylvaticus*. Tufted Wood Bitter-vetch. Linn. Sp. Pl. 1029. Sm. Fl. Brit. n. 2. Engl. Bot. t. 518. Lightf. Scot. 390. t. 16. (Vicia caſſubica; Fl. Dan. t. 98, but not of Linnæus.)—Stems branched, decumbent, hairy. Leaves pinnate, with numerous ovato-lanceolate, hairy leaflets. Stipulas half-arrowſhaped. Legume ovate, with about three ſeeds.—Native of the northern parts of Britain, as well as of Denmark and France, flowering in May or June. The *root* is ſtrong and perennial. *Stems* numerous, angular, proſtrate, branched after flowering. The very numerous and ſmall, hairy, ovate *leaflets* diſtinguiſh this ſpecies from all the foregoing. The *flowers* alſo are many in each cluſter, pale buff, veined with purple. But perhaps the moſt eſſential character conſiſts in the ſhortneſs and breadth of the *legume*, in which reſpect, as well as habit, this plant accords better with many *Viciæ* than with the preſent genus.

A truly wonderful variety of *O. ſylvaticus* was found by the late Mr. Todd, on hills near Hafod, Cardiganſhire, the admired ſeat of T. Johnes, eſq. M.P. In this the *leaves* are ſimple and ſolitary, from five to ten times the ſize of the uſual leaflets, and more obtuſe. Though this variety has been much cultivated, it has never yet been known to produce flowers.

15. O. *ochroleucus*. Buff Bitter-vetch. Willd. n. 13. Waldſtein and Kitaibel Pl. Rar. Hungar.—Stem branched, erect, hairy. Leaves pinnate, with numerous, ſmooth, elliptical leaflets. Stipulas ovato-lanceolate —Native of Hungary. We have ſeen no ſpecimen nor figure. Willdenow ſays it is like the laſt, but abundantly diſtinguiſhed by its erect, leſs hairy *ſtem*, ſmooth *leaflets*, and ovato-lanceolate *ſtipulas*. The *corolla* is pale ſulphur-coloured, or buff.

Profeſſor Martyn deſcribes four more ſpecies, which Miller received from Houſton; but they have not been admitted by any other writer, nor dare we adopt them without ſeeing ſpecimens in order to aſcertain their genus.

Orobus, in *Gardening*, contains plants of the hardy, herbaceous, fibrous-rooted, perennial flowery kind, of which the ſpecies cultivated are: the upright bitter-vetch (O. lathyroides); the yellow bitter-vetch (O. luteus); the ſpring bitter-vetch (O. vernus); the tuberous bitter-vetch (O. tuberoſus); the black bitter-vetch (O. niger); and the Pyrenean bitter-vetch (O. pyrenaicus).

Of the third there are varieties with purple flowers, with pale blue flowers, with deep blue flowers.

The fourth ſort is ſometimes called *wood-pea* and *heath-pea*.

Method of Culture.—All the ſorts are capable of being increaſed by ſeeds and parting the roots. The ſeed ſhould be ſown in the beginning of the autumn, as in September or October, in the clumps, borders, or other parts where they are to remain, or on a bed of good earth, to be afterwards pricked out and tranſplanted. The plants ſhould be kept perfectly free from weeds.

The roots of the large plants may be parted in the autumn, and immediately planted out where the plants are to grow. The ſmall roots may be ſet in nurſery rows, to remain till ſufficiently ſtrong for being finally planted out.

They are all hardy flowering ornamental plants for the borders, clumps, and other parts of pleaſure grounds.

OROCONITES, in the *Materia Medica*, a name given by Hippocrates, and others, to a bulbous root that is recommended as a rich food. It has the name from the Greek ορος, *a mountain*, and κονιτες, *of a conic figure*. This ſhews that it was a root of ſuch a ſhape, found growing in mountainous places; but the learned have been puzzled in their attempts to find out what it was.

ORODADA, in *Geography*, a town of Peru, on the coaſt; ſix miles S.W. of Payta.

OROE, an iſland of Denmark, at the S. end of the Little Belt, about twelve miles long, and two wide; eight miles S.W. of the iſland of Funen. N. lat. 54° 59′. E. long. 10° 20′.

OROESKIOBING, a ſea-port of Denmark, ſituated on the E. ſide of the iſland of Oroe. N. lat. 54° 58′. E. long. 10° 23′.

OROMASDES, in *Mythology*. See Orosmades.

OROMOECTO, in *Geography*, a river of New Brunſwick, which runs into St. John's river, N. lat. 45° 48′. W. long. 66° 40′, and by which the Indians have a communication with Paſſamaquoddy bay.

OROMTCHI, a town of Thibet; 48 miles E. of Manas-Hotun. N. lat. 44° 58′. E. long. 86° 44′.

ORON, or *Oron la Ville*, a town of Switzerland, in the canton of Berne; ſix miles N. of Vevai.

ORONDOCKS, an Indian tribe who live near Trois Rivières, and who could furniſh, between 30 and 40 years ago, 100 warriors.

ORONHI, a town of Thibet, 38 miles W. of Yolotou-Hotun.

ORONO'S Island, a ſmall iſland in the river Penobſcot.

ORONSAY, one of the weſtern iſlands of Scotland, which is a ſmall iſland only at high water, on the N. coaſt of North Uiſt, of which it makes a part at low water. N. lat. 57° 39′. W. long. 7° 16′.

ORONTES, or Axius, a river of Syria, which ſprung towards N. lat. 33° 30′, between Libanus and Antilibanus, and ran into the Mediterranean, about ſix leagues below Antioch. It watered, in its courſe towards the north, Emeſa, Epiphania, Apamea, Antioch, and ſeveral other towns. This river was formerly the moſt conſiderable in Syria; but Volney repreſents it as a rivulet rather than a river. The channel of the Orontes, as well as that of the Jordan, ſays this traveller, are ſcarcely 60 paces wide at their mouths, and if the Orontes were not impeded by ſucceſſive obſtacles, it would be quite dry during the ſummer. It derives its importance in winter from rains and melted ſnows, but during the remainder of the year, its courſe would hardly be diſcovered if it were not marked by the round ſtones and fragments of rocks with which its bed is filled. This river, and alſo the other ſtreams of Syria, are nothing but torrents and caſcades; and it may be conceived, from the proximity of the mountains, among which they riſe, to the ſea, that their waters have not time to collect in long valleys, ſo as to form rivers. If the mouth of the Orontes were cleared, boats might be towed up this river, though they could not ſail up, on account of the rapidity of its ſtream; and thus Antioch would better ſerve as an emporium to the Europeans than Aleppo. The natives, who never knew the name Orontes, call it, on account of the ſwiftneſs of its ſtream, "El-Auſi," rendered by the Greeks "Axius," that is, the rebel. At Antioch its breadth is about 40 paces. Seven leagues above that town it paſſes by a lake abounding with fiſh, and eſpecially eels; great quantities of which are ſalted every year, though not ſufficient for the numerous faſts of the Greek Chriſtians.

ORONTES, a mountain of Aſia, in Media, near Ecbatana. Ptolemy.

ORONTIUM, in *Botany*, ὀροντιον of the Greeks, a name whoſe etymology is loſt in the darkneſs of antiquity. It is ſaid to have belonged to an herb uſed in baths, or fomentations, for the jaundice, and ſome have ſuſpected it to be a corruption of *Origanum*. Profeſſor Martyn ſuggeſts that the word may have come from ὀραω, *to ſee*; which is founded on the ſuppoſition of the plant's being uſeful to the eye-ſight. The ſame name has been given to a ſpecies of *Antirrhinum*; but this ſeems to have originated in the Dutch appellation of the laſt-mentioned genus, *orant*, eaſily aſſimilated to *Orontium* Linnæus appears to have laid hold of it, as an unoccupied name, for the preſent genus, which Mitchell had called *Aronia*, from its partial reſemblance probably to *Arum*. Whether the ſimilarity of ſound led Linnæus to this application, we will not preſume to determine.. Linn. Gen. 172. Schreb. 229. Willd. Sp. Pl. v. 2. 199. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 306. Juſſ. 25. Lamarck Illuſtr. t. 251.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Piperitæ*, Linn. *Aroideæ*, Juſſ.

Gen. Ch. reformed. *Cal.* none, except the *bracteas* be taken for *ſpathas*. *Cor.* in ſix deep, concave, obtuſe, angular ſegments, inflexed at the points, the three alternate ones rather the ſmalleſt, permanent. *Stam.* Filaments ſix, inſerted into the ſegments of the corolla, flat, linear, equal, ſhorter than the corolla; anthers roundiſh, of two lobes, burſting at the top. *Piſt.* Germen ſuperior, large, roundiſh, depreſſed; ſtyle none; ſtigma roundiſh, cloven. *Peric.* Drupa roundiſh. *Seed.* Nut large, ſolitary, of a bony ſubſtance.

Eſſ. Ch. Corolla inferior, in ſix deep inflexed ſegments. Stamens flat, inſerted into the corolla. Style none. Drupa with one bony ſeed.

Obſ. We have endeavoured to correct the generic character, from a compariſon of both the known ſpecies. Dr. Buchanan met with a plant in Nepal, there called *Tilcuſta*, whoſe habit is preciſely that of *O. japonicum*, but the *bracteas* are very long, and the *fruit* a berry of three cells, with ſix ſeeds when in perfection, though indeed ſome of both are moſtly abortive.

1. O. *aquaticum*. Aquatic Orontium. Linn. Sp. Pl. 463. Amœn. Acad. v. 3. 17. t. 1. f. 3. Willd. n. 1. Ait. n. 1.—Leaves floating, ſtalked.—Native of rivers and pools in North America. Cultivated in ciſterns at Kew, where it flowers in June and July. The *root* is perennial, deſcending deep into the mud. *Herb* ſmooth, like a *Potamogeton* in its mode of growth. *Leaves* floating, elliptic-lanceolate, acute, entire, a ſpan long, with numerous parallel ribs. *Spikes* ſolitary, on long ſimple *ſtalks*, whitiſh under the ſpike, which is about an inch long, cylindrical, very denſe, of numerous, crowded, ſeſſile, greeniſh-white *flowers*, with a ſhort concave membranous *bractea* under each flower. The *germen* ſoon becomes very large, depreſſed, dark green, with a large white horny *ſeed*, which we have ſeen in a half-ripe ſtate only, ſo that we are not acquainted with the appearance or texture of the pericarp at an advanced period.

2. O. *japonicum*. Japan Orontium. Thunb. Japon. 144. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 898. Banks Ic. Kæmpf. t. 12. (Kirò et Rirjo, vulgò Omotto; Kæmpf. Am. Exot. 785.)—Leaves erect, dilated and ſheathing at the baſe.—Native of Japan, growing in waſte ground, and allowed to occupy ſuch corners in gardens as would otherwiſe be bare. It is a hardy perennial at Kew, flowering very early in the ſpring. The *root* is thick and long, with numerous ſtrong ſimple fibres. *Stem* none. *Leaves* numerous, erect, coriaceous, ſmooth, ribbed, convoluted, about a foot high, with a dilated ſheathing baſe. *Spikes* ſolitary, on ſhort, ſimple, round, upright, radical *ſtalks*, each *ſpike* about an inch and half long, cylindrical, obtuſe, very denſe, of numerous, crowded, greeniſh-yellow *flowers*, the inflexed broad ſummits of whoſe crowded *petals* give the whole a teſſellated aſpect. Kæmpfer deſcribes the *fruit* the ſize and ſhape of a ſmall olive, ſcarlet, nauſeous, with a heart-ſhaped bony *ſeed*. The *bracteas* are ſhort, rounded, and membranous, like thoſe of the firſt ſpecies.

OROOLONG, in *Geography*, the name of one of the Pelew iſles, on which Capt. Wilſon was wrecked. See PELEW.

OROONOKO, ORINOKO, or *Orinoco*, a large river of South America, diſtinguiſhed by its very ſingular and perplexed courſe. According to La Cruz it riſes in the ſmall lake of Ipava, N. lat. 5° 5′, and thence winds almoſt in a ſpiral form; firſt paſſing to the S.E. it enters the lake of Parima, and iſſues by two outlets on the N. and S. of that lake towards the W., but after receiving the Guaviari, it bends N., then N.E., till it enters the Atlantic ocean by an extended delta oppoſite to the iſle of Trinidad; but the chief eſtuary is conſiderably to the S.E. of that iſland. Many large rivers flow into the Oroonoko; and beſides its ſingular form, it has other remarkable peculiarities. From the S.E. of the lake of Parima, which ſeems to be a kind of inundation formed by the Oroonoko, the White river, called alſo that of Parima, joins the Black river, and thence the great flood of the Maranon. Another ſtream, called the Siaba, flows from the S.W. of the lake into the Black river, and joins another ſtream, which directly connects the Maranon with the Oroonoko. There is alſo a communication between the Black river and the Maranon, by the Joa Parana; ſo that there are three communications between theſe three great rivers. In the year 1800, the Pruſſian traveller, Humboldt, reſolved to explore the reported fact of the junction of the Oroonoko with the Maranon, by the great river Negro. He entered the Orinoco by the river Apuri, and after encountering many difficulties reached the fort of San Carlos, towards the Portugueſe frontier. From this fort he returned to the Orinoco by the river Caſiquiari, a very ſtrong branch of the Orinoco, which communicates with the river Negro. This navigation was rendered fatiguing and dangerous by the force of the current, the prodigious number of moſquitoes and ants, and the want of population, 300 leagues having been travelled by him without ſeeing a human countenance. He entered the Orinoco by the Caſiquiari at 3° 30′, and remounted the current of the Orinoco to Eſmeralda, the laſt Spaniſh ſettlement in that quarter. This remarkable communication had been marked in his map by Samſon de Fer, geographer to his Catholic majeſty in 1713, and confirmed by the able Condamine.

The mouths of the Orinoco are of perilous navigation, and require an expert pilot. Seven of them are navigable for large veſſels; but the chief is the great mouth, about ſix leagues wide, being the moſt ſouthern, and in the direct courſe of the river. The iſles of the Orinoco, or rather its Delta, which is of prodigious extent, are poſſeſſed by the Guaranos and the Mariuſas, two independent tribes of Indians. The river Caroni, running from the S. to the N. for nearly 100 leagues, is celebrated in the expedition of Raleigh. It preſerves its clearneſs for half a league after it joins the Orinoco, having moſtly run over a fine black ſand.

The beauty and grandeur of the banks of the Orinoco ſurpaſs all deſcription. Foreſts of the moſt ſuperb verdure are crowded with birds and monkies of the moſt various and

brilliant colours; and ſometimes immenſe plains form an horizon of 20 or 30 leagues. The annual inundation of the Orinoco begins in April and ends in Auguſt, and in the northern part ſometimes extends for 20 or 30 leagues, during a length of 200. This grand extent it will retain for the whole month of September. The uſual ſwell at San Tomé, or Old Guiana, founded in 1586, on the ſouthern bank of the Orinoco, 50 leagues from its mouth, but transferred in 1764 to a more ſafe poſition about 90 leagues from the ſea, is of 13 fathoms. In October the flood declines; and the river is loweſt in February. The Cayman, which is ſtrictly neither an alligator nor a crocodile, is a terrible inhabitant of the Orinoco.

During the great floods, the river Orinoco, where it paſſes a range of mountains at a place called Angoſtura or the ſtrait, riſes not leſs than 40 varas or Spaniſh yards. Of the ſavages on the Orinoco, Gumilla publiſhed, in 1745, an intereſting account. The nation of the Caberres exceeds the Caribs in courage and power. They are famous for the uſe of a mortal poiſon, and in his time were ſituated on the Guaviari. The Otomacs, in the ſame quarter, raiſe their dead after the expiration of 12 months, and tranſport the bones to a general tomb. Their women aſſerted that to cover their nakedneſs inſpired them with ſhame, as it led to ideas of turpitude unknown before. The Otomacs are accuſtomed to eat earth, as Humboldt has recently obſerved. But, in fact, they only preſerve their grain, fiſh, turtle, &c. in earth, and eat the whole mingled, ſo that a ſtranger would imagine that they devoured earth. This is done with a view to keep their victuals freſh; and the pieces afterwards dug from the pits reſemble bricks. Some of them are ſaid to eat 1½lb. of this earth *per* day. On the Orinoco moſt of the dialects are derived from the Betoya or Jirara, and the Cariba. Moſt of the tribes are ſmall, from 500 to 2000 warriors; but the Caribs boaſt of 12,000, and the Caberres were more numerous. The fury of the Caribs is not more deſtructive than domeſtic poiſon. Many mothers deſtroy their female children, to deliver them from the miſeries ſuffered by women in a ſavage ſtate; and they even regard this practice as an office of tender affection. If we except the Otomacs, the Caberres, and the Caribs, the other tribes moſtly flee when one or two fall in battle. All are deceitful and addicted to falſhood. In general, theſe ſavages bathe twice a day, thus obſerving a practice that conduces both to health and pleaſure. The mouth, or main channel of the Orinoco, is laid down in N. lat. 8° 30′. W. long. 59° 50′. Pinkerton's Geography, vol. iii.

Oroonoko, *Little*. See Mocomoco.

OROPESA, the capital of the juriſdiction of Cochabamba, in South America, ſituated on a ſmall river in a valley. The inhabitants trade with their corn and fruits, which are produced in conſiderable quantities in the valley, where their town is ſituated; 150 miles N.W. of La Plata. S. lat. 18° 15′. W. long. 67° 6′.—Alſo, a town of Spain, in New Caſtile; 52 miles W. of Toledo.—Alſo, a town of Spain, in Valencia, on the coaſt of the Mediterranean; 32 miles E.N.E. of Segorbe. N. lat. 40° 8′. W. long. 0° 4′.

Oropesa, *Cape*, a cape of Spain, on the coaſt of Valencia. N. lat. 40° 7′. E. long. 0° 1′.

OROPUS, in *Ancient Geography*, a town of Aſia, in Syria, ſaid to have been built by Nicator. Steph. Byz.—Alſo, a town of Macedonia.—Alſo, a town of Attica, near the ſea-coaſt. The inhabitants of this town were the firſt who reckoned Amphiaraus in the number of the gods, and the other Greeks followed their example. At 12 ſtadia from the town was a temple of this deity. Amphiaraus excelled in the interpretation of dreams, and he delivered his predictions in hexameter verſes.—Alſo, a town of Greece, in the iſland of Eubœa, in which was a temple conſecrated to Apollo.—Alſo, a town of the Peloponneſus, in the Argolide.—Alſo, a town of Greece, in Theſprotia, of which town Nicopolis was probably a part.

OROSEI, in *Geography*, a town of Sardinia, on the E. coaſt; 58 miles E. of Alghieri.

OROSIUS, Paul, in *Biography*, a prieſt of Tarragona, in Catalonia, flouriſhed in the beginning of the fifth century. He was in early life a diſciple of St. Auguſtin. In the year 414 he was ſent by two Spaniſh biſhops into Africa, to requeſt aid from St. Auguſtin againſt the heretics who diſturbed their churches. He remained a year with that prelate, and under his guidance made a great progreſs in the ſtudy of the ſcriptures. In 415 Oroſius was ſent by him on a miſſion to St. Jerome at Jeruſalem, and brought from thence into Africa a number of relics. It was at the deſire of St. Auguſtin that he undertook to write a hiſtory from the creation to the year 416, the object of which was to refute the calumnies of the Pagans againſt Chriſtianity. He accordingly compiled, in ſeven books, a view of general hiſtory, which he is ſaid to have entitled "De Miſeria Hominum." His ignorance of the Greek language involved him in many miſtakes. Oroſius was author likewiſe of "A Defence of the Freedom of the Will," againſt the Pelagians, and other works. The "Hiſtory" has gone through ſeveral editions, of which the beſt is, unqueſtionably, that of Havercamp, 1738. A tranſlation of it by our immortal Alfred is ſtill extant, in which it has the title "Hormeſta," but the reaſon for this change in the title has not been aſcertained. Bayle. Moreri.

OROSMADES, Oromasdes, or *Oromazes*, in *Mythology*, a deity among the Perſians, which is deemed the principle, or author of good, in the ſyſtem of Zoroaſter, revived by the Manichees. Oroſmades produced the good ſpirits and the ſtars, and encloſed them in an egg, which was broken by Arimanius; whence proceeded confuſion, and a mixture of good and evil. But after many conflicts the good deity totally vanquiſhes the evil one. See Arimanius.

OROSPEDA, or Ortospeda, in *Ancient Geography*, a mountain of Spain, in which were the ſprings of the river Bœtis, according to Strabo, who adds, that it was inhabited by the Oretani. This mountain is ſituated in the province of Grenada, on the borders of Seville.

OROSPIZA, in *Ornithology*, a name by which the ancient naturaliſts call the brambling, or mountain-finch.

The word is Greek, and expreſſes *mountain-chaffinch*. See Montifringilla.

OROSWEG, in *Geography*, a town of Hungary, the ſee of a biſhop; 8 miles N. of Munkacz.

OROVITZA, a town of Sclavonia; 14 miles N.N.E. of Poſzega.

OROUST, an iſland in the North ſea, near the W. coaſt of Sweden, 40 miles in circumference. N. lat. 58° 10′. E. long. 11° 30′.

ORPELLO, a preparation of braſs uſed in the glaſs trade, and prepared in this manner: cut plates of braſs into ſmall pieces, and place them in a luted crucible in a ſtrong fire, but not ſo violent as to melt it. Let it ſtand in this manner for four days, in which time it will be well calcined; when cold, powder and ſift it, and finally grind it on a porphyry. This will be a black powder; ſpread this on tiles, which place on burning coals in the leer, near the hole, for four days; take off the aſhes that may fall into it, and finally powder and ſift it fine for uſe. It is known to be

nicely prepared, when, on mixing with the melted metal in the glaſs furnace, it makes it ſwell and boil.

The colour it gives is a very elegant ſky-colour, and a ſea-green, or a mixt colour, between them, according to the quantity and degree of calcination. Neri's Art of Glaſs, p. 35.

ORPHAN, a child, or minor, deſtitute of father; or that has neither father nor mother.

Hence the Taborites, or followers of Ziſca, finding themſelves, at his death, without chief or conductor, took the appellation of *orphans*.

Among the Athenians, the orphans whoſe fathers had loſt their lives in the ſervice of their country, were under the guardianſhip of the polemarchus, who was to provide them with a competent maintenance out of the public treaſury.

In the city of London there is a court of record eſtabliſhed for the care and government of orphans. The lord-mayor and aldermen of London have the cuſtody of orphans under age, and unmarried, of freemen that die; and the keeping of all their lands and goods; and if they commit the cuſtody of an orphan to any man, he ſhall have a writ of *raviſhment of ward*, if the orphan be taken away; or the mayor and aldermen may impriſon the offender, until he produces the infant. If any one, without the conſent of the court of aldermen, marries ſuch an orphan under the age of twenty-one years, though out of the city, they may fine and impriſon him until paid.

Executors and adminiſtrators of freemen dying, are to exhibit true inventories of their eſtates before the lord-mayor and aldermen in the court of orphans, and give ſecurity to the chamberlain of London and his ſucceſſors, by recognizance, for the orphan's part; which if they refuſe to do, they may be committed to priſon until they obey.

The lord-mayor and commonalty of London being anſwerable for the orphans' money paid into the chamber of the city, and by ſome accidents become indebted to the orphans and their creditors, in a greater ſum than they could pay; it was enacted by 5 & 6 W. and M. cap. 10. that the lands, markets, fairs, &c. belonging to the city of London, ſhall be chargeable for raiſing 8000*l.* to be appropriated for a perpetual fund for orphans; and towards raiſing ſuch a fund, the mayor and commonalty may aſſeſs 2000*l.* yearly upon the perſonal eſtates of the inhabitants of the city, and levy the ſame by diſtreſs. A duty is alſo granted of 4*s.* *per* ton on wines imported, and on coals, and every apprentice ſhall pay 2*s.* 6*d.* when he is bound, and 5*s.* when he is admitted a freeman, for raiſing the fund, which is to be applied for payment of the debts due to orphans, by intereſt, after the rate of 4 *per cent.*

By the cuſtom of London, the ſhare of the children, or orphanage part, is not fully veſted in them till the age of twenty-one, before which they cannot diſpoſe of it by teſtament, and if they die under that age, whether ſole or married, their ſhares ſhall ſurvive to the other children; but after the age of twenty-one, it is free from any orphanage cuſtom, and, in caſe of inteſtacy, ſhall fall under the ſtatute of diſtributions. See CUSTOM *of London.*

ORPHAN *Iſland*, in *Geography*, an iſland of America, at the mouth of the Penobſcot, containing about 10,000 acres of excellent tillage land.

ORPHAN's *Bank*, a fiſhing-bank off the S.E. point of Chaleur's bay, on the N.E. coaſt of New Brunſwick, on which is from 75 to 30 fathoms water.

ORPHAN's *Iſland*, an iſland in lake Ontario, lying off the E. ſhore of Maryſburg, and near to it, in Traverſe bay.

ORPHANUS, in *Natural Hiſtory*, a name given by ſome authors to a poor ſpecies of opal, called by ſome *pſeudo-opalus*; it has no other colours beſide a milky-white, and purpliſh-red. This ſtone is frequent in Germany, and Hungary.

ORPHEON, a ſtringed inſtrument, turned with a wheel like the vielle, which it very much reſembles.

ORPHEORON, a ſtringed inſtrument of muſic, ſmaller than the pandora, but which it entirely reſembles. It is tuned like the lute: its higheſt or firſt ſtring is G.

ORPHEOTELISTÆ, Ορφεοτελισται, in *Antiquity*, perſons initiated in the Orphic myſteries. They aſſured all that were admitted into their ſociety of certain felicity after death. (See ORPHEUS.) At their initiation, little elſe was required of them beſides an oath of ſecrecy.

ORPHEUS, in *Grecian Hiſtory*, and *Mythology*, is one of the moſt ancient and venerable names among the poets and muſicians of Greece. His reputation was eſtabliſhed as early as the time of the Argonautic expedition, in which he was himſelf an adventurer: and is ſaid by Apollonius Rhodius, not only to have incited the Argonauts to row by the ſound of his lyre, but to have vanquiſhed and put to ſilence the Sirens, by the ſuperiority of his ſtrains. Yet, notwithſtanding the great celebrity he had ſo long enjoyed, there is a paſſage in Cicero, which ſays, that Ariſtotle, in the third book of his Poetics, which is now loſt, was of opinion that ſuch a perſon as Orpheus never exiſted; but as the work of Cicero, in which this paſſage occurs, is in dialogue, it is not eaſy to diſcover what was his own opinion upon the ſubject, the words cited being put into the mouth of Caius Cotta. And Cicero, in other parts of his writings, mentions Orpheus as a perſon of whoſe exiſtence he had no doubts. There are ſeveral ancient authors, among whom is Suidas, who enumerate five perſons of the name of Orpheus, and relate ſome particulars of each. And it is very probable that it has fared with Orpheus as with Hercules, and that writers have attributed to *one* the actions of *many*. But however that may have been, we ſhall not attempt to collect all the fables that poets and mythologiſts have invented concerning him. They are too well known to need inſertion here. We ſhall, therefore, in ſpeaking of him, make uſe only of ſuch materials as the beſt ancient hiſtorians, and the moſt reſpectable writers among the moderns, have furniſhed towards his hiſtory.

Dr. Cudworth, in his "Intellectual Syſtem," after examining and confuting the objections that have been made to the being of an Orpheus, and, with his uſual learning and abilities, clearly eſtabliſhing his exiſtence, proceeds, in a very ample manner, to ſpeak of the opinions and writings of our bard, whom he regards not only as the firſt muſician and poet of antiquity, but as a great mythologiſt, from whom the Greeks derive the Thracian religious rites and myſteries.

"It is the opinion," ſays he, "of ſome eminent philologers of later times, that there never was any ſuch perſon as Orpheus, except in Fairy-land; and that his whole hiſtory was nothing but a mere romantic allegory, utterly devoid of truth and reality. But there is nothing alleged for this opinion from antiquity, except the one paſſage of Cicero concerning Ariſtotle, who ſeems to have meant no more than this, that there was no ſuch poet as Orpheus anterior to Homer, or that the verſes vulgarly called Orphical were not written by Orpheus. However, if it ſhould be granted that Ariſtotle had denied the exiſtence of ſuch a man, there

ſeems to be no reaſon why his ſingle teſtimony ſhould preponderate againſt the univerſal conſent of all antiquity, which agrees, that Orpheus was the ſon of Oeager, by birth a Thracian, the father, or chief founder of the mythological and allegorical theology amongſt the Greeks, and of all their moſt ſacred religious rites and myſteries; who is commonly ſuppoſed to have lived before the Trojan war, that is, in the time of the Iſraelitiſh judges, or at leaſt to have been ſenior both to Heſiod and Homer, and to have died a violent death, moſt affirming that he was torn in pieces by women. For which reaſon, in the viſion of Herus Pamphylius, in Plato, Orpheus's ſoul, paſſing into another body, is ſaid to have choſen that of a ſwan, a reputed muſical animal, on account of the great hatred he had conceived for all women, from the death which they had inflicted on him. And the hiſtoric truth of Orpheus was not only acknowledged by Plato, but alſo by Iſocrates, who lived before Ariſtotle, in his oration in praiſe of Buſiris; and confirmed by the grave hiſtorian, Diodorus Siculus, who ſays, that Orpheus diligently applied himſelf to literature, and when he had learned τα μυθολογεμενα, or the mythological part of theology, he travelled into Egypt, where he ſoon became the greateſt proficient among the Greeks, in the myſteries of religion, theology, and poetry. Neither was this hiſtory of Orpheus contradicted by Origen, when ſo juſtly provoked by Celſus, who had preferred him to our Saviour; and, according to Suidas, Orpheus the Thracian was the firſt inventor of the religious myſteries of the Greeks, and that religion was thence called Threſkeia, as it was a Thracian invention. On account of the great antiquity of Orpheus, there have been numberleſs fables intermingled with his hiſtory, yet there appears no reaſon that we ſhould diſbelieve the exiſtence of ſuch a man."

The biſhop of Glouceſter ſpeaks no more doubtfully of the exiſtence of Orpheus, than of Homer and Heſiod, with whom he ranks him, not only as poet, but alſo as a theologian, and founder of religion. This learned author has thrown new lights upon the character of Orpheus; our purſuits are ſomewhat different; it was his buſineſs to introduce him to his readers as a philoſopher, a legiſlator, and a myſtagogue; and it is ours, after eſtabliſhing his exiſtence, to rank him among the firſt cultivators of muſic and poetry, and to give him that exalted and reſpectable ſtation among illuſtrious bards, which has been allowed him by almoſt all antiquity.

The family of Orpheus is traced by ſir Iſaac Newton for ſeveral generations: "Seſac paſſing over the Helleſpont, conquers Thrace, kills Lycurgus, king of that country, and gives his kingdom, and one of his ſinging women, to Oeagrus, the ſon of Tharops, and father of Orpheus; hence Orpheus is ſaid to have had the muſe Calliope for his mother."

He is allowed by moſt ancient authors to have excelled in poetry and muſic, particularly the latter, and to have early cultivated the lyre, in preference to every other inſtrument; ſo that all thoſe who came after him were contented to be his imitators; whereas he adopted no model, ſays Plutarch; for before his time no other muſic was known, except a few airs for the flute. Muſic was ſo cloſely connected in ancient times with the moſt ſublime ſciences, that Orpheus united it not only with philoſophy, but with theology. He abſtained from eating animal food, and held eggs in abhorrence as aliment, being perſuaded that the egg ſubſiſted before the chicken, and was the principle of all exiſtence: both his knowledge and prejudices, it is probable, were acquired in Egypt, as well as thoſe of Pythagoras, many ages after.

The paſſage in which Ariſtotle is ſaid to have denied the exiſtence of Orpheus is loſt, and it now reſts on Cicero's quotation, who afterwards, in other works, reſtores him to life. With reſpect to his abſtaining from the fleſh of oxen, Geſner ſuppoſes it to have proceeded from the veneration ſhewn to that animal, ſo uſeful in tillage, in the Eleuſinian myſteries, inſtituted in honour of Ceres, the goddeſs of agriculture. And with reſpect to theology, Diodorus Siculus tells us that his father Oeagrus gave him his firſt inſtructions in religion, imparting to him the myſteries of Bacchus, as they were then practiſed in Thrace. He became afterwards a diſciple of the Idæi Dactyli, in Crete, and there acquired new ideas concerning religious ceremonies. But nothing contributed ſo much to his ſkill in theological matters as his journey into Egypt, where, being initiated into the myſteries of Iſis and Oſiris, or of Ceres and Bacchus, he acquired a knowledge concerning initiations, expiations, funeral rites, and other points of religious worſhip, far ſuperior to any one of his age or country. And being much connected with the deſcendants of Cadmus, the founder of Thebes in Bœotia, he reſolved, in order to honour their origin, to tranſport into Greece the whole fable of Oſiris, and apply it to the family of Cadmus. The credulous people eaſily received this tale, and were much flattered by the inſtitution of the ceremonies in honour of Oſiris. Thus Orpheus, who was held in great veneration at the Grecian Thebes, of which he was become a citizen, admirably adapted this fable, and rendered it reſpectable, not only by his beautiful verſes, and manner of ſinging them, but by the reputation he had acquired of being profoundly ſkilled in all religious concerns.

At his return into Greece, according to Pauſanias, he was held in the higheſt veneration by the people, as they imagined he had diſcovered the ſecret of expiating crimes, purifying criminals, curing diſeaſes, and appeaſing the angry gods. He formed and promulgated an idea of a hell, from the funeral ceremonies of Egyptians, which was received throughout all Greece. He inſtituted the myſteries and worſhip of Hecate among the Eginetes, and that of Ceres at Sparta.

Profane authors look upon Orpheus as the inventor of that ſpecies of magic, called *evocation of the manes*, or raiſing ghoſts; and indeed the hymns which are attributed to him are moſtly pieces of incantation and real conjuration. Upon the death of his wife Eurydice, he retired to a place in Theſprotia, called Aornos, where an ancient oracle gave anſwers to ſuch as evoked the dead. He there fancied he ſaw his dear Eurydice, and at his departure flattered himſelf that ſhe followed him; but upon looking behind him, and not ſeeing her, he was ſo afflicted, that he ſoon died of grief.

There were perſons among the ancients who made public profeſſion of conjuring up ghoſts, and there were temples where the ceremony of conjuration was to be performed. Pauſanias ſpeaks of that which was in Theſprotia, where Orpheus went to call up the ghoſt of his wife Eurydice. It is this very journey, and the motive which put him upon it, that made it believed he went down into hell.

The poets have embelliſhed this ſtory, and given to the lyre of Orpheus, not only the power of ſilencing Cerberus, and of ſuſpending the torments of Tartarus, but alſo of charming even the infernal deities themſelves, whom he rendered ſo far propitious to his intreaties, as to reſtore to him Eurydice, upon condition that he would not look at her, till he had quitted their dominions; a bleſſing which he ſoon forfeited, by a too eager and fatal affection.

"All

" All dangers paſt, at length the lovely bride
In ſafety goes, with her melodious guide;
Longing the common light again to ſhare,
And draw the vital breath of upper air:
He firſt, and cloſe behind him follow'd ſhe,
For ſuch was Proſerpine's ſevere decree.
When ſtrong deſires the impatient youth invade,
By little caution, and much love betrayed:
A fault which eaſy pardon might receive,
Were lovers judges, or could hell forgive.
For near the confines of etherial light,
And longing for the glimmering of a ſight,
Th' unwary lover caſt a look behind,
Forgetful of the law, nor maſter of his mind.
Straight all his hopes exhal'd in empty ſmoke;
And his long toils were forfeit for a look."

Dryden's Virgil.

Tzetzes explains the fable of his drawing his wife Euridice from hell by his great ſkill in medicine, with which he prolonged her life, or, in other words, ſnatched her from the grave. Æſculapius and other phyſicians have been ſaid to raiſe from the dead thoſe whom they had recovered from dangerous diſeaſes.

The biſhop of Glouceſter, in his learned and admirable account of the Eleuſinian myſteries, ſays, " While theſe myſteries were confined to Egypt, their native country, and while the Grecian lawgivers went thither to be initiated, as a kind of deſignation to their office, the ceremony would be naturally deſcribed in terms highly allegorical. This way of ſpeaking was uſed by Orpheus, Bacchus, and others; and continued even after the myſteries were introduced into Greece, as appears by the fables of Hercules, Caſtor, Pollux, and Theſeus's deſcent into hell; but the allegory was ſo circumſtanced, as to diſcover the truth concealed under it. So Orpheus is ſaid to get to hell by the power of his harp:

" Thrëichius fretus citharâ, fidibuſque canoris."

Virg. Æn. vi. ver. 119.

that is, in quality of lawgiver; the harp being the known ſymbol of his laws, by which he humanized a rude and barbarous people. Had an old poem, under the name of Orpheus, entitled " A Deſcent into Hell," been now extant, it would perhaps have ſhewn us, that no more was meant than Orpheus's *initiation*."

Many ancient writers, in ſpeaking of his death, relate, that the Thracian women, enraged at being abandoned by their huſbands, who were diſciples of Orpheus, concealed themſelves in the woods, in order to ſatiate their vengeance; and, notwithſtanding they poſtponed the perpetration of their deſign ſome time through fear, at length, by drinking to a degree of intoxication, they ſo far fortified their courage as to put him to death. And Plutarch aſſures us, that the Thracians ſtigmatized their women, even in his time, for the barbarity of this action.

Our venerable bard is defended by the author of the " Divine Legation," from ſome inſinuations to his diſadvantage in Diogenes Laertius. " It is true," ſays he, " if uncertain report was to be believed, the myſteries were corrupted very early; for Orpheus himſelf is ſaid to have abuſed them. But this was an art the debauched myſtæ of later times employed to varniſh their enormities; as the deteſted pederaſts of after ages ſcandalized the blameleſs Socrates. Beſides, the ſtory is ſo ill laid, that it is detected by the ſureſt records of antiquity: for in conſequence of what they fabled of Orpheus in the myſteries, they pretended he was torn in pieces by the women; whereas it appeared from the inſcription on his monument, at Dium in Macedonia, that he was ſtruck dead by lightning, the envied death of the reputed favourites of the gods."

This monument, at Dium, conſiſting of a marble urn on a pillar, was ſtill to be ſeen in the time of Pauſanias. It is ſaid, however, that his ſepulchre was removed from Libethra, upon mount Olympus, where Orpheus was born, and was thence transferred to Dium by the Macedonians, after the ruin of Libethra, by a ſudden inundation, which a dreadful ſtorm had occaſioned. This event is very minutely related by Pauſanias.

Virgil beſtows the firſt place in his Elyſium upon the legiſlators, and thoſe who brought mankind from a ſtate of nature into ſociety.

" Magnanimi heroës, nati melioribus annis."

At the head of theſe is Orpheus, the moſt renowned of the European lawgivers; but better known under the character of poet: for the firſt laws being written in meaſure, to allure men to learn them, and, when learnt, to retain them, the fable would have it, that by the force of harmony, Orpheus ſoftened the ſavage inhabitants of Thrace:

" —— Thrëicius longa cum veſte ſacerdos
Obloquitur numeris ſeptem diſcrimina vocum:
Jamque eadem digitis, jam pectine pulſat eburno."

Æn. lib. vi. ver. 645.

The ſeven ſtrings given by the poet in this paſſage to the lyre of Orpheus, is a circumſtance ſomewhat hiſtorical. The firſt Mercurian lyre had, at moſt, but four ſtrings. Others were afterwards added to it by the ſecond Mercury, or by Amphion; but, according to ſeveral traditions preſerved by Greek hiſtorians, it was Orpheus who completed the ſecond tetrachord, which extended the ſcale to a heptachord, or *ſeven ſounds*, implied by the *ſeptem diſcrimina vocum*: for the aſſertion of many writers, that Orpheus added two new ſtrings to the lyre, which before had ſeven, claſhes with the claims of Pythagoras to the invention of the octachord, or addition of an eighth ſound to the heptachord, which made the ſcale conſiſt of two disjunct, inſtead of two conjunct tetrachords, and of which almoſt all antiquity allows him to have been the inventor. Nor is it eaſy to ſuppoſe, that the lyre ſhould have been repreſented in ancient ſculpture with four or five ſtrings only, if it had had nine ſo early as the time of Orpheus, who flouriſhed long before ſculpture was known in Greece.

Orpheus is mentioned by Pindar in his fourth Pythic. The paſſage is curious: " Orpheus," ſays he, " ſpeaking of the Argonauts, joins theſe heroes; Orpheus, father of the lyre and of ſong; Orpheus, whom the whole univerſe celebrates, and whoſe ſire is Apollo." Herodotus likewiſe ſpeaks of the Orphic myſteries. His hymns, ſays Pauſanias, were very ſhort, and but few in number; the Lycomides, an Athenian family, knew them by heart, and had an excluſive privilege of ſinging them, and thoſe of their old poets, Muſæus, Onomacritus, Pamphus, and Olen, at the celebration of the Eleuſinian myſteries; that is, the prieſthood was hereditary in this family.

Iamblicus tells us, that the poems under the name of Orpheus were written in the Doric dialect, but have ſince been trans-dialected, or moderniſed. It was the common opinion in antiquity that they were genuine; but even thoſe who doubted of it, gave them to the earlieſt Pythagoreans, and ſome of them to Pythagoras himſelf, who has frequently been

been called the follower of Orpheus, and been ſuppoſed to have adopted many of his opinions.

If we have ſelected with too much ſedulity and minuteneſs whatever ancient and modern writers relative to Orpheus have ſaid, it has been occaſioned by an involuntary zeal for the fame of this muſical and poetical patriarch; which, warm at firſt, grew more and more heated in the courſe of enquiry; and ſtimulated by the reſpect and veneration which we found paid to him by antiquity, we became a kind of convert to the myſtagogue, and eagerly aſpired at initiation into his myſteries, in order to reveal them to our reader.

The true doctrine of Orpheus on the ſubject of Coſmogmy is ſaid to be contained in an epitome made long ago by Timotheus, the chronographer. This writer ſays, that Orpheus gave an account of the generation of the gods, the creation of the world, and the formation of man, profeſſing, that he delivered nothing from his own invention, but as he was informed, on inquiry, by Phœbus, Titan, or the Sun. His account is briefly as follows: that in the beginning the ether, or heaven, was formed by God; and that on each ſide of the ether were chaos and dark night, which covered whatſoever was under the ether, thereby ſignifying, that night was prior. He declared alſo, that there was a certain incomprehenſible being, which was the higheſt and moſt ancient of all things, and the maker of the univerſe, both of the ether itſelf, and of things under the ether; that the earth was inviſible by reaſon of the darkneſs which was upon it; but the light, breaking forth through the ether, illuminated the whole creation; this light, which ſo broke forth, being ſaid by him to be that higheſt of all beings before-mentioned, whoſe name, as revealed by the oracle, was Counſel, Light, and the Giver of Life: that theſe three names manifeſt one and the ſame power and might of that inviſible and incomprehenſible God, who is the maker of all things, and who bringeth that which is not, into a ſtate of exiſtence; by which power were procured all incorporeal principles, and the ſun, the moon, the ſtars, the earth, and the ſea, and all things therein, both viſible and inviſible. He likewiſe declared, that mankind was formed out of the earth by the ſame Deity, and received from him a rational ſoul, agreeably to what Moſes has recorded. Timotheus adds, that the ſame Orpheus alſo wrote, that all things were made by one godhead of three names, and that this God is all things. (Timoth. Chronogr. apud Euſeb. Chron. Græc. Vide etiam Suidam, in voce Orpheus; and Procl. in Tim. lib. ii.) If this teſtimony be admitted, we need not appeal to the Orphic verſes, which are very full as to the aſſertion of a Supreme Deity. Many of theſe verſes, it is true, are ſuppoſititious, and manifeſtly forged either by Chriſtians or Jews; but the ſame cannot be ſaid of them all: ſeveral being cited by Pagan authors, as having been written, if not by Orpheus himſelf, yet by perſons of great antiquity, and well acquainted with his doctrine and traditions, and, therefore, thought, by men of good learning and judgment, genuine, and worthy of ſome regard. (Cudworth Intel. Syſt.) However, Orpheus's theology has been preferred to that of the other heathens by the Chriſtian fathers; and an ingenious writer (Burnet, Archæolog. lib. i.) has ſurmiſed, that his eſtabliſhing of polytheiſm was owing rather to the neceſſity he was under of complying with the ſtupidity of the barbarous people, whom he firſt civilized, than his own approbation; being obliged to give them, not the religion which he himſelf beſt approved, but ſuch a one as they were capable of receiving. It is further obſervable with regard to the doctrine of this ancient poet, that he was the firſt who taught the Greeks the doctrine of the primitive egg, whence all other beings proceeded (Plut. in Symp. Macrob. Sat. l. vii. c. 16.); an opinion very ancient, which, without doubt, he had learned from the Egyptians, who, as well as thoſe of ſeveral other nations, repreſented the world under this emblem. This ſymbol was adopted and employed by the Phœnicians, Chaldeans, Perſians, Indians, and even the Chineſe; nor is it improbable, that this was the primary opinion of all who undertook to explain the formation of the world.

Brucker, in his "Hiſtory of Philoſophy by Enfield," (vol. i.) has deduced from the Orphic verſes and other fragments of Orpheus the following ſummary of the doctrine of Orpheus concerning God and nature. "God, from all eternity, contained within himſelf the unformed principles of the material world, and conſiſted of a compound nature, active and paſſive. By the energy of the active principle, he ſent forth from himſelf, at the commencement of a certain finite period, all material and ſpiritual beings, which partake, in different degrees, of the divine nature. All beings, proceeding originally from God, will, after certain purgations, return to him. The univerſe itſelf will be deſtroyed by fire, and afterwards renewed." He adds, an Orphic fragment is preſerved by Athenagoras, in which the formation of the world is repreſented under the emblem of an egg; formed by the union of night, or chaos, and ether, which at length burſt, and diſcloſed the forms of nature. The meaning of this allegory probably is, that by the energy of the divine active principle upon the eternal maſs of paſſive matter, the viſible world was produced. Some writers have aſcribed to Orpheus the doctrine ſince maintained by Spinoza, which confounds the Deity with the Univerſe, making him the Το Παν. But the doctrine of emanation, which ſuppoſes that the principles of all things were originally in God, and at length flowed from him, is conſonant to the general tenor of the Orphic fragments, and is the more likely to have been the real doctrine of Orpheus, as it prevailed, in the moſt remote times, through the Eaſt, and paſſed thence to the North. The human ſoul, Orpheus, after the Thracians and Egyptians, from whom he derived his philoſophy, held to be immortal. Diodorus Siculus relates, that he was the firſt who taught (that is, among the Greeks) the doctrine of the future puniſhment of the wicked, and the future happineſs of the good. That this doctrine was commonly received among the followers of Orpheus appears from the ſubjoined anecdote. A prieſt of Orpheus, who was exceedingly poor and wretched, boaſting to Philip of Macedon that all who were admitted into the Orphic myſteries would be happy after death; Philip ſaid to him, "Why then do you not immediately die, and put an end to your poverty and miſery?"

The planets and the moon, Orpheus conceived to be habitable worlds, and the ſtars to be fiery bodies like the ſun: he taught that they are animated by divinities; an opinion which had been commonly received in the Eaſt, and which was afterwards adopted by the Pythagoreans, and other Grecian philoſophers.

Orpheus, in *Ichthyology*, the name of a fiſh caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its eyes are large and prominent, and its teeth ſerrated; it has only one fin on the back, and the anterior rays of that are prickly, and others ſoft to the touch; its anus is ſmall, and is ſaid to have no paſſage for the ſemen.

This was the fiſh called orpheus by the ancients, but the modern Greeks call another fiſh by that name. It is a ſpecies of the ſparus, of a flat figure, but very thick, has a ſmall mouth, and is covered with ſmall, but very rough

ſcales,

ſcales, which adhere very firmly to the fleſh; the tail is not forked; it has fleſhy lips, and very ſmall teeth; its back and ſides are black; its belly white; it has a large black ſpot at the root of the tail; its head is reddiſh, and its fins are very elegantly diverſified with various colours; it has only one back-fin, and that has the anterior ray prickly, the hinder ones not at all ſo. It grows ſometimes to twenty pounds weight, and is much eſteemed among the modern Greeks.

ORPHIGNES, Fr. *Orphics*, in *Literature* and *Hiſtory*. By orphics are generally underſtood the poems and detached verſes which the ancients and moderns have aſcribed to Orpheus.

ORPIERRE, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the diſtrict of Gap; 7 miles S. of Serres. The place contains 858, and the canton 2965 inhabitants, on a territory of 115 kiliometres, in eight communes.

ORPIMENT, in *Chemiſtry* and the *Arts*, a yellow mineral, from which the colour called king's yellow is prepared. It is a compound of ſulphur and arſenic. See ARSENIC, *Sulphuret of*.

ORPINE, in *Botany*, &c. See SEDUM and TELEPHIUM.

ORR, in *Geography*, a town of Arabia, in the province of Yemen, the reſidence of a Dola; 24 miles W.S.W. of Sana.

ORR *Water*, a river of Scotland, which runs into Solway Frith, 10 miles E. of Kircudbright, N. lat. 54° 55′. W. long. 3° 50′.

ORRA, a mountain of Arabia, in Yemen; 20 miles N.E. of Abu-Ariſch.

ORRACH, or ORACH, in *Botany*. See ORACH.

ORRERY, in *Aſtronomy*, a machine for repreſenting by wheelwork the various motions of the heavenly bodies. This machine differs from a planetarium in this reſpect, that it exhibits the diurnal as well as annual motions of the earth, the revolution of our moon, and ſometimes the rotation of the ſun and of certain planets on their axes, as well as the revolutions of the latter, whereas a planetarium produces only the revolutions of the primary planets round the ſun. The larger, or what has been called the "Grand Orrery," exhibits moreover the motions of the ſecondary planets, but more particularly thoſe of Jupiter. To conſtitute an orrery, it is not neceſſary, however, that the motions of all the primary planets ſhould be included, provided the different motions of our planet, the earth, and of her ſecondary, the moon, be included; becauſe on theſe motions depend all the problems that relate to geography, navigation, and aſtronomy, the earth being the ſituation, though a moveable ſituation, from which all the phenomena are viewed, that ſucceſſively ariſe out of the different motions of the other diſtant bodies, conſidered as contemporary with the motions of the earth herſelf. Hence all the viciſſitudes of ſummer and winter, of ſpring and autumn, of day and night, the riſings, ſettings, and culminating of the heavenly bodies, together with their conſtantly varying altitudes and azimuths, their right aſcenſions, declinations, and amplitudes, their conjunctions and oppoſitions, their tranſits and occultations or eclipſes, conſtitute matter of illuſtration for the orrery, which renders it a machine of the firſt importance in ſcience; and when all the wheelwork is ſo accurately calculated and properly arranged, that the motions in the machine are exact repreſentations of the true motions of the heavenly bodies themſelves, it affords one of the moſt pleaſing, as well as inſtructive, objects of contemplation that human ingenuity has contrived, inaſmuch as it comprehends in miniature the outlines of the whole ſolar ſyſtem, and explains in a familiar manner a multiplicity of intereſting particulars relating to the compoſition of the univerſe; particulars which have required centuries to diſcover, and the ſkill of ſucceſſive mathematicians ſatisfactorily to explain.

It is not our intention to give in this place a hiſtory of all the machines that have been contrived by human ſkill, to illuſtrate the different ſyſtems of planetary motion, which the ancient philoſophers of different nations adopted, as the reſult of their imperfect obſervations and reaſoning; many of which will be introduced in hiſtorical order, under our more general article PLANETARY *Machines*, to which the reader is referred; but to deſcribe ſuch machines only, as illuſtrate the true or Copernican ſyſtem, agreeably to the definition we have given of an *orrery*, as diſtinguiſhed from a *planetarium*, the latter of which will alſo be fully deſcribed in its place. See PLANETARIUM.

The internal conſtruction of an orrery has hitherto been conſidered as compoſed of mechaniſm too complex to be intelligibly deſcribed in a dictionary of the arts and ſciences, but we flatter ourſelves, that our diviſion of the different planetary machines into appropriate articles, and our having deſcribed the theory of planetary calculations, and of planetary mechaniſm under the heads EQUATION *Mechaniſm*, and NUMBERS *Planetary*, will enable us to remove objections of this nature, and to render perfectly intelligible, not only the effect produced by any particular contrivance, but the reſults accruing from the united agencies of all the mechanical parts of any of the machines, that appear to be worthy of minute deſcription.

The appellation of *orrery* conveys in itſelf no idea indicative of the nature or uſe of the machine that it deſignates, but aroſe out of the following circumſtance. About the year 1715 an inſtrument was contrived and made by Mr. George Graham, that repreſented at the ſame time both the annual and diurnal motions of the earth, and alſo the ſynodic period of the moon, which motions had never before been exhibited together by any mechanical contrivance, at leaſt in England. This inſtrument was put into the hands of a workman to be packed and ſent to prince Eugene, along with ſome other inſtruments. Whether this workman was Rowley, or ſome other perſon employed by him, does not appear; but it is ſaid that he copied the model put into his hands, and from it Rowley made a machine for the *earl* of *Orrery*, with additions of his own invention. Sir Richard Steel, who knew nothing of Mr. Graham's inſtrument, wiſhing to do juſtice to the inventor, as he thought, of ſuch an ingenious and complicated piece of mechaniſm, named it an *orrery*, and attributed to Rowley the honour which was due to Graham. This is Dr. Deſaguliers's account of the origin of the orrery, from which it may be inferred, that Graham invented the parts of the machine which relate to the earth and moon, and that Rowley added thoſe which produce the motions of the other planets; but whether the inferior planets only, or the ſuperior alſo, were at firſt added, does not certainly appear. We have been favoured with a minute inſpection into, and examination of, the orrery that was made from Rowley's plan many years ago for an Indian nabob, by order of the Eaſt India company, but which was never ſent out by reaſon of the ſaid nabob's death. This machine has not the wheelwork for exhibiting the ſuperior planets, but correſponds with the drawing given in Bion's book of mathematical inſtruments, and alſo with the ſhort notice which is there given of its external parts and uſe. The caſe is of ebony, ſurmounted by an ecliptic circle of ſolid ſilver, 1⅝ inches broad and 29 inches in diameter, on which are neatly engraved the graduated ſigns of the ecliptic,

tic, and a circle of declination, but no months, or days of the month: this ecliptic circle is ſupported by twelve pillars, apparently of ſolid ſilver, and the twelve ſides of the caſe have each an appropriate animal of ſilver to correſpond to the twelve ſigns; the intervening corners being ornamented with as many ſilver pilaſters, each ſix inches long, in the form of caryatides. Theſe expenſive ornaments around the exterior of the caſe, are calculated to raiſe the expectation that the interior parts may have been contrived and arranged with peculiar attention to accuracy, but the account we have to ſubjoin, we fear, will diſappoint the reader. It would not be an eaſy matter to convey, by a verbal deſcription, a clear notion of the relative ſituations and proportions of all the wheels, pinions, bars, and other internal parts of the mechaniſm, as preſented to the eye when the cover is removed; nor is it neceſſary in order to give a true account of their accuracy; but our examination of the numbers of teeth contained in the various wheels and pinions, and of the manner in which thoſe moſt eſſential parts are placed to perform their reſpective offices, has enabled us to make ſuch a correct report, as we truſt will be intelligible to ſuch of our readers as have peruſed with attention our article NUMBERS *Planetary*, where the different modes of appreciating the value of wheelwork, acting under different circumſtances, are exemplified.

We propoſe to deſcribe Graham's portion of the machine firſt, as being the moſt eſſential, as well as of prior date, and then to add our deſcription of Rowley's, together with ſuch remarks as ſeem neceſſary to explain the conſtruction of each portion.

Graham's Portion.—In examining this orrery, we began our operations by finding out what ſort of connection the handle has with the diurnal motion of the earth, which motion, in all machines of this nature, is made the ſtandard by which all the other periods are examined and eſtimated. We found fifteen wheels and pinions employed in communicating the motion of the handle to the earth's axis: but as none of theſe were found to be concerned in the train conſtituted of the ratio between a day and a year, they are no otherwiſe worthy of particular notice, than as being many of them ſuperfluous, and as giving a falſe reckoning of the number of the earth's diurnal rotations. In order to indicate ſolar time correctly, it is neceſſary that the hour index on the earth's axis, or wherever it is placed, ſhould revolve round a fixed face once in every rotation of the earth round its axis, or otherwiſe, that the face ſhould revolve, with a fixed index, in this period: but in the inſtance before us, the handle or arbor of the index is in a ſtationary poſition, while it is connected, by the intervention of the wheels in queſtion, with the earth's axis, as borne by the annual bar, and placed therefore in a variable ſituation, as it regards the ſun, the centre of its motion; from which arrangement an annual difference of four entire days ariſes in the motions of the handle and of the earth; which may be thus explained: one of the wheels, which takes the motion of the handle, and conveys it to the earth's annual arm, is neceſſarily concentric with the ſun's ſtem, and has the ſaid arm revolving round it in a year; its number of teeth is 96, and the pinion which it actuates has 24 teeth: this pinion has its teeth in action with thoſe of wheel 96, while it is carried round in the annual orbit, and therefore experiences a ſubtraction of $\frac{96}{24}$, or four entire revolutions, not contemplated by the contriver, or if contemplated not remedied; which ſubtraction, acting in a direction contrary to that of the motion derived from the handle alone, makes the earth have four rotations in the year fewer than the index counts on the horary circle. The error thus occaſioned in the indication of time, however, attaches fortunately to the handle, and not to the earth's axis, the motion of which is governed by the annual train. We notice this circumſtance the more particularly, becauſe Bion has given an erroneous account of this part of the mechaniſm, when he ſays, that "one entire turn of the handle of this inſtrument anſwers to the diurnal motion of the earth about its axis," which aſſertion has hitherto been generally credited. Nay, to an accurate examiner it is evident, without an inſpection of the means, that a correct effect is not produced in counting time by the hour plate, for the circle of hours placed at the earth's axis makes 91 revolutions only, while the handle makes 92 nearly. But this error is not of ſo much importance in the motion of the handle as it would have been in the earth, or hour circle, while the two latter are correſpondent. The wheelwork, which conſtitutes the effectual part of the ratio between a year and a day, are $\frac{18}{24} \times \frac{481}{1} = \frac{8766}{24} = 365\frac{1}{4}$, ſo that the year is a civil, not a ſolar year, which a true repreſentation requires. The wheel of 24 teeth, connected with the earth's axis, drives that of 18, on the arbor of which is a ſingle endleſs ſcrew acting with the large wheel of 487, which wheel is $17\frac{3}{4}$ inches diameter, and fixed faſt, ſo as to reſiſt the power of the ſcrew, which is therefore itſelf obliged to move, and the annual frame along with it, the ſpace of $\frac{1}{487}$ of a circle in every 18 hours, or time of a revolution of the ſpiral thread. The ſhape of the teeth of this large wheel is that of a common ſaw, and it has evidently been divided and cut without an engine, for the dividing marks are ſtill viſible. The paralleliſm of the earth's axis is preſerved by means of five wheels, of each 60 teeth, the firſt of which is fixed on the central arbor of the large wheel of 487, and the others are carried by the annual frame, ſo that they revolve each in a civil year, except the fixed one, which is the cauſe of motion to all the reſt; the ſecond and fourth wheels revolve in a forward, and the third and fifth in a backward direction; conſequently the paralleliſm is perfect, but might have been effected with fewer wheels.

The wheelwork for the moon's period is $\frac{35}{12} \times \frac{75}{49} \times \frac{153}{25}$ of a day, the value of which train is $27^d\ 7^h\ 42^m\ 51.^s42$, and the error in exceſs is $13.^s26$. This period, it will be obſerved, is a periodic, not a ſynodic revolution, and it required ſome obſervation, as well as ſkill in planetary calculations, to aſcertain firſt how the ſynodic revolution, or lunation, is effected by wheelwork, that anſwers to a periodic revolution, and ſecondly, the preciſe length of that ſynodic revolution: in the firſt place, the periodic is converted into a ſynodic revolution thus; ſome of the wheels of the moon's train are placed upon the wheel that preſerves the earth's parallelism, which wheel, we have ſaid, has a backward motion once in a civil year; it conſequently carries its load of wheels round the earth once in a year, in a retrograde direction: but the laſt wheel of the train, which has 153 teeth, is a ring indented on the interior circle, and moves concentric with the earth, in a period that would be $27^d\ 7^h\ 42^m\ 51.^s42$, if it experienced no drawback in each revolution: but the pinion of 25, which actuates this wheel of 153, is annually carried backwards by the wheel of parallelism, while its teeth are in action, and therefore the wheel of 153 has its periodic motion, ariſing from the train ſimply conſidered, retarded by one

one entire revolution in a year; or, in other words, by the drawback in queſtion, one entire revolution of the moon, as ſhe regards the earth, is ſubtracted in every year, which ſubtraction, being effected gradually, makes every lunation longer than it otherwiſe would have been, by leſſening the whole number of revolutions: let us ſee, ſecondly, if this tranſmutation of the periodic into a ſynodic revolution be performed with requiſite accuracy; $27^d\ 7^h\ 42^m\ 51.^s42$ are equal to $27.^d321428$, by which, if we divide 365.25, the period of the earth's revolution, the quotient 13.368628 will expreſs the number of periodic revolutions, as effected by the train of wheelwork excluſively: then if we deduct unity, the effect of one retrograde revolution in a year, produced by the wheel of parallelism, we ſhall have 12.368628 for the number of lunations in the ſame time, by which, if we again divide 365.25, we ſhall have 29.53035 nearly, or $29^d\ 12^h\ 43^m\ 42.^s7$ for the time elapſed between two ſucceſſive conjunctions of the moon, which lunation is quicker than a true one, as taken from the aſtronomical tables, by $20.^s1$.

The wheels for the motion of the moon's nodes plate, are $\frac{26}{98} \times \frac{93}{26} = \frac{93}{98}$, the retrograde period of which is $\frac{93}{5} = 18\frac{3}{5}$ years, or $6793^d\ 15^h\ 36^m$ (ſee NUMBERS *Planetary*), which period is too ſhort by $4^d\ 13^h\ 17^m$ nearly, or a ſpace in the ecliptic of $14'\ 28\frac{1}{4}''$, correſponding to this time. This error, in ſo ſlow a motion, is not indeed very conſiderable, as it is $18\frac{3}{5}$ years in amounting to leſs than a quarter of a degree. The wheel of 98 is made faſt to the annual wheel of parallelism, and, by means of a pair of intermediate wheels of 26 teeth each, pinned together on the ſame arbor, communicates its motion to the wheel 93, which revolves once in a year, and $\frac{5}{93}$, or five teeth more, which exceſs above one revolution, in a retrograde direction, as it regards the moon's motion in her orbit, amounts to an entire backward revolution in the period already ſpecified, which is therefore the time of retrogradation of the nodes of the lunar orbit. An inclined circular rim is carried by the wheel 93, as the repreſentative of the moon's orbit, and the ſtem of the moon reſting on its plane, riſes and falls alternately, as the moon performs her ſynodic period, and indicates the latitude engraved on the face of the rim in queſtion, which contrivance has been ever ſince adopted by the Engliſh inſtrument-makers. The wheelwork for making the moon keep her illuminated phaſe towards the ſun in all parts of her orbit, by means of a little black ſemiglobular cap, is $\frac{20}{86} \times \frac{28}{6} = \frac{560}{516}$, which at firſt view appeared to be very erroneous, ſeeing the cap ought to revolve juſt once in each lunation; but a little examination ſoon convinced us that an allowance is here alſo to be made for a tranſpoſition of ſome of the wheels in each month; the wheel of 86, or firſt wheel of the train, is made faſt to the annual wheel of parallelism, and the reſt of the wheels are borne by the lunar ring of 153 teeth, before deſcribed, which it has been ſeen revolves in a forward direction, once in each lunation; when the train is reduced to the ſimple form $\frac{560}{516}$, the 560 repreſents the lunar wheel 28, and the 516 the wheel of 86 on the annual bar, and to aſcertain how much the former is accelerated by the backward tranſpoſition of the latter, we muſt ſay as $365\frac{1}{4}^d : 516 :: 29.^d53035 : 42$ nearly, ſo that in each month the product (which may be called the wheel) 560 is accelerated, as much as if 516 had been $516 + 42 = 558$, and the whole value of the train $\frac{560}{558}$ without tranſpoſition: but to make the parallelism complete, the products of the drivers and of the driven wheels ought to have been alike, which they are not by $\frac{2}{560}$; the deviation from perfect accuracy is, however, of leſs moment than it would have been in one of the planetary periods, becauſe the cap is eaſily adjuſtable whenever the error becomes ſenſible.

After this examination and report of Graham's portion of the orrery, which is the moſt eſſential part, it will appear remarkable to the reader, that the inventor ſhould have gained as much credit from his expenſive and cumberſome conſtruction of a machine, in which neither accuracy nor ſimplicity has been attained, as if he had contrived a perfect repreſentation of the earth's and moon's motions in the ſimpleſt and moſt accurate manner; but the fact ſeems to have been, that the complexity of the conſtruction has hitherto ſo puzzled every examiner of its internal mechaniſm, that all attempts to aſcertain the periods correſponding to the wheelwork employed therein have proved ineffectual, until we undertook to diſcloſe the value of each train by ſyſtematic rules, that we truſt are intelligible by ordinary readers; and we beg to avow our diſintereſted love of truth, by aſſerting that, ſo far as we have examined this machine, it "has paſſed for more than it is worth."

Rowley's Portion.—The inſtrument-maker whom Dr. Deſaguliers mentions as having added portions of his own to Graham's orrery, to render it more comprehenſive, was, as we have ſaid, Rowley, whoſe name is familiar among the inſtrument-makers of the preſent day: the portion which probably was firſt attached, as an appendage to Graham's, was the mechaniſm for effecting the ſun's rotation, and the revolutions of the inferior planets, Mercury and Venus, to complete the ſyſtem as far as to the earth's orbit incluſively; accordingly theſe are the parts of the orrery before us which remain to be deſcribed; but before we enter upon the examination and deſcription, it may prepare the reader for what he has to expect, to premiſe, that the artiſt with whom we have now to do, has not profited much in point of ſimplicity from a contemplation of his predeceſſor's complexity of mechaniſm; they neither of them have borne in mind the uſeful maxim, that "more means are not neceſſary than are ſufficient to produce an end;" but it may be alleged as an excuſe for our preſent artiſt, that it is eaſier to deviſe and make a new inſtrument with all its dependent parts as a whole, than to adopt the ideas and calculations of another artiſt, and make them, imperfect as they may be, the baſis of further calculations for additional movements, that did not enter into the original deſign; which is the difficulty under which Rowley muſt have laboured, when he undertook to introduce into Graham's machinery the wheelwork for the ſun and inferior planets.

We will begin with the movement of the ſun, which is $\frac{94}{1} \times \frac{12}{60} \times \frac{26}{26} \times \frac{24}{24} \times \frac{60}{36}$, but we may omit the portion $\frac{26}{26} \times \frac{24}{24}$, as being of no value in the calculation, and ſerving only to transfer the motion communicated to them; then the remaining or effective portion of the wheelwork will be $\frac{94}{1} \times \frac{12}{60} \times \frac{60}{36}$, or $\frac{94}{1} \times \frac{12}{36} = 31\frac{1}{3}$, which are ſo many days by reaſon of the ſingle ſcrew denoted by unity revolving in a day, and this would have been the exact period of a rotation

a rotation produced by the mechaniſm, if the wheels had been all in a permanent ſituation; but becauſe many of them are carried by the earth's annual bar round the ſun, whilſt their connection with the laſt moving or central wheel of 60 is preſerved, an additional motion is thus produced in it, independently of the proper motion depending on the preceding calculation, which additional motion or *acceleration* may be thus eſtimated; the wheel of 94 revolves once in every year by means of its poſition on the annual bar, and alſo that of 60, which is contemporary by being placed on the ſame common arbor; but the pinion of 12 is actuated by this laſt wheel $\frac{60}{12}$, or five times round in a year, as is alſo its contemporary wheel of 36, which again drives the laſt wheel of 60; hence $5 \times 36 = 180$ teeth of the laſt wheel are brought into action by theſe means in every year; but the laſt wheel has got only 60 teeth, therefore $\frac{180}{60} = 3$ are ſo many entire rotations *per annum* produced by the *manner* in which the mechaniſm is placed, beſides the 11.625, or $\frac{365.25}{31.33}$ rotations occaſioned by the proper action of the train; the whole number of rotations, therefore, are $11.625 + 3 = 14.625$, by which, if we divide 365.25 days, we ſhall obtain $24^d\ 23^h\ 23^m\ 4.^s6$ for the whole period of the ſun's rotation, as produced by the conjoint operations of the train and annual bar.

In the ſame way muſt the whole periods of the two inferior planets be aſcertained; for the long train which actuates the ſun's rotation is common to both theſe until we arrive at the laſt pair of each: the movement of Mercury, if we put down again all the wheels concerned in producing the motion of this planet, will ſtand thus, $\frac{94}{1} \times \frac{12}{60} \times \frac{26}{26} \times \frac{24}{24} \times \frac{88}{15}$, the effective portion of which is $\frac{94}{1} \times \frac{12}{60} \times \frac{88}{15} = 110.293$ days for the period produced in the regular way: the acceleration here, eſtimated in the ſame way as that of the ſun was, is 5×15, or 75 teeth in the laſt wheel, or wheel of 88; conſequently $\frac{75}{88} = .8522727$ of a revolution conſtitutes the *acceleration* in this caſe, which added to 3.3116234 $\left(\text{or } \frac{365.25}{110.293}\right)$ revolutions produced by the regular action of the train, amounts to 4.1638961 revolutions *per annum*; and $\frac{365.25}{4.1638961} = 87^d\ 14^h\ 47^m\ 24.^s9$ is the whole period ariſing out of the compound motion.

Again, the other planet Venus has for a whole train $\frac{94}{1} \times \frac{12}{60} \times \frac{26}{26} \times \frac{24}{24} \times \frac{225}{15}$, or in effect $\frac{94}{1} \times \frac{12}{60} \times \frac{225}{15} = 282$ days without the acceleration, which in this inſtance is $\frac{75}{225}$, or $\frac{1}{3}$d of a revolution; we have then $\frac{365.25}{282} = 1.295212$ revolutions without the acceleration or quantity .333333, which together make 1.628545 revolutions *per annum*, or one revolution in $\frac{365.^d25}{1.628545}$, or in $224^d\ 6^h\ 36^m\ 59.^s72$ from the joint effect of both cauſes of motion.

We are not quite certain whether or not the reader will fully comprehend the nature of the acceleration here deſcribed, from any verbal deſcription that could be given; but the artiſt who may have opportunity to notice the wheels in motion, will have no difficulty, after peruſing this account, in completely underſtanding the ſeparate ſources of motion, however he might have been previouſly perplexed to aſſign to each its due quantum of the joint effect.

And now that we have arrived at the reſult of our examination, it appears by a compariſon of theſe periods with the exact times of the reſpective revolutions, collected from the aſtronomical tables, that they are by no means ſo accurate as might have been expected from ſuch elaborate calculations, and ſuch complex mechaniſm.

Beſides theſe portions of mechaniſm, there are ſome wheels connected with the ſun's axis, which carry round a ſupport for a little lamp, to be kept always ſix ſigns from, or oppoſite to the earth, and to illuminate one of its hemiſpheres, when a three inch globe is put on as the earth's repreſentative, which is an occaſional apparatus; the uſual globe being $1\frac{1}{4}$ inch ball of ivory; the movement, to anſwer this purpoſe, is $\frac{12}{60} \times \frac{73}{1}$ of the ſun's rotation, *viz.* $\frac{876}{60}$ of $24.97435 = 364^d\ 15^h\ 0^m\ 44^s$, which deviates from what it ought to be, about 15 hours motion in a year; but this deviation is of little conſequence, as the intention of the lamp is only to illuminate the earth, while the viciſſitudes of day and night, and the ſucceſſion of the ſeaſons, &c. are under conſideration. The lamp has a convex lens placed, we preſume, at the diſtance of its focal convergence from the light, ſo that the rays which paſs through may proceed parallel to each other to the little globe.

The laſt wheels, or rather rings of Mercury and Venus, have their planes inclined, ſo that the ſtems which bear the planetary balls, being ſcrewed into them, riſe and fall reſpectively, as the rings revolve by means of friction-rollers, for the purpoſe of ſhewing the variations of latitude; they are alſo placed a little excentrically with reſpect to the ſun. The perihelion diſtance of Mercury is $2\frac{1}{4}$, and the aphelion diſtance $2\frac{9}{10}$ inches by meaſurement, which ſhould have been very nearly to each other as 4 to 6: Venus is at the mean diſtance $5\frac{1}{2}$, and the Earth $9\frac{1}{4}$. As it has been before obſerved, there is no graduated circle for indicating the day of the month, ſo that this inſtrument, we muſt conclude, was never intended to point out the *particular day* on which any phenomenon is exhibited, but merely to give a general repreſentation of celeſtial appearances; which purpoſe, notwithſtanding its inaccuracies, it is calculated to do in a pleaſing manner by the aid of its external appearance. We cannot diſmiſs the conſideration of this machine, without remarking further one peculiarity which ſtruck us on firſt counting the teeth of the two laſt wheels in each of Rowley's movements; which for Mercury are $\frac{88}{15}$, for Venus $\frac{225}{15}$, and for the Sun $\frac{60}{36} = \frac{25}{15}$. It occurred to us at the time of examination, that the laſt movers were intended to repreſent exact days; the periods being to each other in the neareſt whole numbers, as 25, 88, and 225 reſpectively; and we are ſtill of opinion that the artiſt intended they ſhould be ſo during his labours; for it is much more probable that theſe numbers were *firſt fixed upon*, and afterwards connected with the diurnal motion

by intermediate wheels to anſwer this purpoſe in the beſt way that could be deviſed, than that ſuch complex data, as a compound motion affords, ſhould be fixed upon for the ground-work of the calculations: indeed it is improbable in the extreme that *all* the laſt wheels, ſo circumſtanced, ſhould have been obtained by any regular arithmetical proceſs, other than voluntary aſſumption of theſe numbers, with a determination to make them anſwer by ſubſidiary additions; which circumſtance accounts pretty well for the great number of wheels introduced which form no part of the calculation, and at the ſame time renders it exceedingly probable that the inventor himſelf, not attending ſufficiently to the *compoſition* of the motions, believed that the periods were reſpectively 25, 88, and 225 days, and the probability gains additional ſtrength, from the conſideration that, ſuppoſing the ſun's rotation to be performed in exactly 25 days, the mechaniſm for carrying round the lamp, *viz.* $\frac{12}{60} \times \frac{73}{1}$ of 25 would in that caſe give a revolution in exactly 365 days; which, therefore, moſt likely, was the period intended; indeed ſuch a concurrence of four whole periods without a fraction, under ſuch a complexity of circumſtances, puts the matter almoſt beyond a doubt.

Rowley's grand Orrery, made by Wright.—In the month of July, 1813, we were favoured with a peep into the interior conſtruction of the ſuperb orrery at Richmond obſervatory, made by T. Wright, mathematical inſtrument-maker to his majeſty George II. in the year 1733; it was our intention to have analyſed the wheelwork, ſo as to have taken a particular account of each train, but when the covering parts were taken off, we found that the time allowed us for ſuch labour was inadequate, even if we had been admitted to take the conſtituent portions into detached pieces for examination. The mechaniſm for the Sun, Mercury, and Venus, appeared to be ſimilar to what we have already deſcribed, and could not be minutely inſpected in an attached ſtate, as ſeveral of the wheels were concealed by cocks and other parts that were not allowed to be undone. It was of importance, however, to aſcertain the diurnal and annual wheels of the earth as accurately as we could, ſince the other periods take the earth's motion as the ſtandard of their time. At the firſt peep into the interior of the machine, not only an unexpected multiplicity of wheels preſented themſelves to the eye, but many of them were ſo enormouſly large, that we at firſt deſpaired of being able to count any of their teeth in a ſatisfactory manner; but having with us a pair of ſpring-dividers, we adopted the plan of taking in twenty teeth at once between their points, which ſcheme conſiderably leſſened our labour, and enabled us to bring away with us ſeveral of the numbers. Beyond the orbit of Venus there are nine large concentric rings indented, revolving round rollers placed on ſtuds on the bottom of the machine, and regularly increaſing in diameter till the ninth, or laſt, which is a fixed one, nearly filling the ſpace within the ſurrounding ecliptic, which within is 42 inches in diameter. The handle enters the ſide of the ornamented caſe, and takes hold of an horizontal arbor which lies acroſs theſe rings, but beneath them, having three different contrate wheels faſt to it in ſight, and being connected with ſeveral pinions, in a way not ſeen; ſome of which are ſupported under the bottom plate by a ſliding bar, that brings them into or out of action, with their large rings reſpectively; the contrate wheels alſo will ſlide into or out of action ſeparately. If we begin to count from the largeſt, or fixed rim, calling it one, the ſliding pinions drive the moveable rings thus; a pinion of 9, appearing to revolve, by means of the concealed mechaniſm, in 172 days, or turns of the handle, actuated, when forced home into action, the third ring of 560 teeth; the period correſponding to which numbers is $\frac{560}{9}$ of 172 days = 10702.2. This period we can hardly ſuppoſe to be the exact one intended by the maker of the machine; but if the pinion of 9 be made to revolve 172.8 days, which is equally practicable, then the period thus rectified will be 10746.8 days, nearly as in nature: this ring carries the ball of Saturn, on a ſtem connected with it, at the diſtance of 17.5 inches from the ſun. Again, a pinion of 8, on the concealed ſliding bar, drives the fifth ring of 480 teeth in apparently 72 days; but the correſponding period $\frac{480}{8}$ of 72 = 4320, is too little by 10.6 days: we muſt, therefore, ſuppoſe that the pinion of 8 revolves in $72\frac{1}{4\frac{1}{5}}$ days, and then the rectified period will be 4330.6 days for Jupiter, whoſe ſtem is 12.9 inches from the ſun. For Mars, the ſeventh ring, with 365 teeth, is driven by a pinion of 10 in $\frac{365}{10}$ of 19 days apparently, or in 693.5 days, the planet being at $10\frac{1}{4}$ inches from the ſun; but this is too inaccurate alſo, therefore ſubſtitute 18.82 days for the period of the pinion, and the rectified period will be $\frac{365}{10}$ of 18.82, or 686.93 days, pretty nearly the truth. Thus have we been able to aſcertain the values of the concealed wheels, which may be repreſented very eaſily by wheels of common numbers, deriving their motions firſt from the horizontal diurnal arbor, and then from one another, from the quickeſt to the ſloweſt movers in ſucceſſion. The eighth ring, which is driven by a pinion of 20, always in action, has alſo 365 teeth, and the time in which the pinion revolves was aſcertained to be 20 days, ſo that each tooth of the wheel repreſents an exact revolution of the handle, and alſo, as we ſhall ſoon ſee, a ſolar day: on this wheel the annual arm is ſupported, and likewiſe the mechaniſm for the revolutions of the Sun, Mercury, and Venus, as before deſcribed, but their periods will not be exactly the ſame, becauſe here the year conſiſts of only 365 days; whereas in the ſmaller inſtrument it had $365\frac{1}{4}$ as the ſtandard period. We will return to the diurnal motion, when we have deſcribed the remaining indented rings: the firſt, which we have ſaid is fixed faſt, is uſed for preſerving the parallelism of Saturn's ring, for doing which ſeveral wheels and an endleſs ſcrew are introduced; but as it was only to produce a fraction of high numbers, where the numerator and denominator are neceſſarily alike, we thought it of no importance to count thoſe numbers. The ſecond ring revolves by the action of the firſt contrate wheel on the horizontal diurnal arbor, which has thirty teeth; but as the wheels for producing the periods of the five ſatellites of Saturn (the two neareſt not being then diſcovered), are numerous, and the planes of the orbits improperly placed horizontal, we thought it adviſable to loſe no valuable time in examining them, particularly as no phenomena of importance are illuſtrated thereby; we, therefore, proceeded to Jupiter's ſatellites, which are of more importance in any machine. The fourth ring, from which theſe take their motions, has 540 teeth, driven by the ſecond contrate wheel of 36 placed on the diurnal arbor: again, this ring gives its motion unaltered to a pinion of 21 borne by Jupiter's arm, which pinion, therefore, has a combination of two

motions, one derived from the diurnal arbor, the value of which is $\frac{21}{36}$ of a day, and the other $\frac{540}{21}$ in Jupiter's whole period, in conſequence of the 21 being carried round 540 in that ſpace of time. This portion of the motion is a deduction by reaſon of the pinion receiving a *retrograde* motion from the handle, or cauſe of the quicker motion, but a *direct* motion from Jupiter's ſlow motion in the orbit, and the *difference* of theſe two is the abſolute motion of the pinion before us to be aſcertained: but before we aſcertain this difference, let us ſee what the period would be of the arbor that carries the four drivers of the ſatellites, without conſidering the deduction in queſtion; for in all probability this deduction was not in the mind of the contriver when the numbers were calculated: $\frac{21}{36}$ of a day is juſt 14 hours, for the period of the pinion of 21, on a ſuppoſition of its being in a ſtationary ſituation, and the wheels that tranſmit the motion along Jupiter's arm are in effect $\frac{48}{28}$ or $\frac{12}{7}$, and $\frac{12}{7}$ of 14 hours is 24, or an exact day: on the arbor of the laſt wheel of 48 are placed four drivers to actuate each its fellow in its own period: the pairs are thoſe with the values placed oppoſite them; *viz.*

		D.	H.	M.
1. Satellite	$\frac{84}{48}$ of 24^h	1	18	0
2. Ditto	$\frac{85}{24}$ of 24	3	18	0
3. Ditto	$\frac{86}{12}$ of 24	7	4	0
4. Ditto	$\frac{100}{6}$ of 24	16	16	0

As all the numbers, that we have here examined, have correſponding values in time, without a remainder, and as the time of the firſt mover comes out an exact day, it may be conſidered as certain, that theſe were the refults calculated upon by the contriver, who, in every inſtance throughout the machine, has neglected the conſideration of minutes and ſeconds in his calculations of the periods. But we propoſed to aſcertain the real periods, when the allowance is made for the drawback occaſioned by the motion of Jupiter's arm, which is thus calculated: $\frac{540}{21} = 25.714285$ &c. is the number of revolutions in a forward direction, made by the pinion 21, in Jupiter's period of 4330.6 days, as before determined; then one of theſe revolutions being performed in 14 hours, as we have ſeen, we ſhall have $25.714285 \times 14 = 359.99999$, &c. or 360 hours for the deduction in the aggregate reduced to hours: therefore, as $4330.^d6 : 360^h :: 14^h : 2.^m90673$; that is, if Jupiter's period produce a drawback of 360 hours, one rotation of 14 hours will have a drawback of 2.90673 minutes, which, taken from 14 hours, leaves 13.951555 hours as the corrected period of the pinion of 21 to revolve in, inſtead of 14 hours, which would have been the period if Jupiter had not had a revolution in his orbit. We have now, therefore, the ſubjoined periods from the ſame wheelwork, which are really fractions, not of 24 hours, but of $\frac{48}{28}$ of $13.^h951555$, which comes out $23.^h916951$, or $23^h\ 55^m\ 1^s$. Hence we have,

		D.	H.	M.	S.
1. Satellite	$\frac{84}{48}$ of $23.^h916951$	1	17	51	16
2. Ditto	$\frac{85}{24}$ of ditto	3	12	42	21
3. Ditto	$\frac{86}{12}$ of ditto	7	3	24	17
4. Ditto	$\frac{100}{6}$ of ditto	16	14	36	57

Theſe periods are not ſo accurate as thoſe which we gave before, nor is either of the ſets ſo accurate as might have been expected in a machine of the value of 1500*l.*, which, we were informed by an inſtrument-maker, who was preſent, muſt have been about the original price. The ſixth ring, which has 432 teeth, is impelled by the third contrate wheel on the horizontal diurnal arbor of 46 teeth; and a wheel, or rather pinion of 23, receives the motion through the medium of the ring 432, as was the caſe with Jupiter's 540; and a ſimilar allowance for the drawback is to be made here for the time of revolution of the pinion 23, as was there for the pinion of 21. The period $\frac{23}{46}$ of a day is 12 hours, which would have been the period of the revolution of pinion 23, provided the arm of Mars had not been carried in its revolution round the wheel 432, in his period. But we muſt aſcertain the correct period by calculation, as we did the 21 of Jupiter, thus: $\frac{432}{23} = 18.78260$ are the revolutions to be deducted of each 12 hours, or, which is the ſame thing, 9.3913 days' motion in the time of the period of Mars, which we have taken at 686.93 days. Hence, as $686.^d93 : 9.^d3913 :: 12^h : 0.^h15405$; and the third term, diminiſhed by the ſecond, leaves 11.83595 days as the correct period for the time of a revolution of pinion 23; then, $\frac{24}{50}$ of this time is $24^h\ 39^m\ 29^s$ for the revolution of Mars, which, without the correction, would have been 25 hours exactly, furniſhing another proof of the author's intention.

For want of ſufficient time, we omitted to notice particularly whether or not the planets, Saturn and Jupiter, had their motions round their axes produced by wheelwork, like Mars; but the impreſſion on our mind is, that they had, though we could not take down the numbers at the time.

We return now to the earth's motion, as we propoſed. We have already ſaid, that the large wheel, which revolves in a year, has 365 teeth, and that each tooth repreſents a day. The ninth, and laſt ring that he have to mention, is within this annular ring, and has the ſame number of teeth, namely 365: its uſe is to take a tooth from the contrate wheel of 96, on the diurnal arbor, (or otherwiſe moving contemporary with it,) and to give it to a wheel on the earth's axis, or rather to a wheel on a tube that aſcends to the earth's axis, and that communicates this motion to the axis by the medium of three equal pinions. It was difficult to obtain the number of teeth of the tubed wheel, which at firſt we ſuſpected was 96 alſo; in which caſe, there would have been an error in the diurnal train of $\frac{365}{96}$, or $3\frac{77}{96}$ days

in

in a year, ſimilar to the drawback we have noticed in the caſe of Jupiter's moons, and the rotation of Mars; becauſe while the firſt 96 is ſtationary, and the ſecond moveable, by being put on the annual bar, it is clear that this laſt has a compound motion, compoſed of + 365 from the handle, and $-3\frac{77}{96}$ ariſing from the annual circuit round the ninth ring of 365. To ſatisfy ourſelves as to the reſult of this combination, we turned the handle 365 times, and counted juſt 365 rotations of the earth in the ſame time; which correſpondence convinced us, that there muſt exiſt a compenſation that does not appear at firſt ſight; and it was not till we had returned home, that the means neceſſary for effecting this compenſation occurred to us, but which we are fully ſatisfied are the means adopted. The deduction, we have ſeen, is $3\frac{77}{96}$ revolutions of the wheel on the annual bar, in each 365 days: now $3 \times 96 + 77 = 365$; therefore, this deduction is at the rate of one tooth *per* day: and to balance this deduction of one tooth *per* day, there muſt ſomehow be, by way of balance, an acceleration or addition of one tooth *per* day, which is done ſimply thus: let the tubed wheel, on the earth's annual bar, be 95 inſtead of 96, while the wheel in the fixed ſituation remains as we counted it 96, and the conſequence will be this; the *deduction* will now be $\frac{365}{95}$ $= 3\frac{80}{95}$ revolutions of the earth's axis, by the effect of the annual motion on this wheel of 95, and $3 \times 95 + 80 = 365$, as before; but for every turn of wheel 96, on the diurnal handle, wheel 95 makes an entire rotation, and *one tooth more*, or receives an *addition* of one tooth *per* day, from the diurnal motion only: hence from the diurnal motion ariſes an acceleration of one tooth *per* day in the earth's rotation; but from the annual motion ariſes a retardation of one tooth *per* day, which would not have been the caſe, if the ninth ring, for the tranſmiſſion, had not had as many teeth as days. The balance, therefore, is exact; and it now appears why the wheel for the tranſmiſſion of motion from the 96 to the 95 was made with 365 teeth, in preference to any other number. Nay, if the year had conſiſted of $365\frac{1}{4}$ days, the compenſation would not have been perfect, as we preſume it now is, in conſequence of the numbers we have every reaſon to conclude are adopted, except that we have not actually counted the wheel 95, concealed under the moon's mechaniſm, which we were not authoriſed to diſplace. By this compenſation, the diurnal handle and the earth's axis make each 365 rotations in the year, and the only error remaining would be a quarter of a degree nearly, in each year, in the ecliptic circle, which probably on this account has no annual index, nor any days of the month inſerted. Thus the more minutely we examine the diſtinct portions of this mechaniſm, the more clearly we ſee the reaſons, not only of various contrivances, and of many of the numbers adopted in this particular conſtruction, but alſo of the omiſſions of parts generally deemed neceſſary in more recent conſtructions. The omiſſion of a quarter of a day in the year, and alſo of the daily hand and ecliptic index, is an omiſſion ariſing entirely out of the manner in which the motion of the handle is tranſmitted to the earth's axis, as is alſo the want of a ſidereal horary plate; that of the ſun being made faſt to the cover, ſupported by the annual bar, and the horary index being put on a vertical diurnal arbor at ſome diſtance from the earth, which is an ivory ball of about an inch and half diameter, neatly engraved, with the principal lines and countries on its ſurface, and fitted up with a circle of illumination, and placed at the diſtance of $6\frac{3}{4}$ inches from the ſun; while the diſtances of Venus and Mercury are at $3\frac{1}{4}$ and 2.2 reſpectively. We come, laſtly, to the moon, which performs her lunation in $\frac{96}{24} \times \frac{118}{16}$ of a day, which period is $29^d\ 12^h$; and the inclined plate for the moon's latitude is carried backward, for the motion of the nodes by the wheels $\frac{95}{100}$ in $\frac{95}{5}$, or 19 civil years. The wheels $\frac{93}{98}$, however, which are equally convenient, would have produced a much more accurate reſult in $18\frac{3}{5}$ years. A cap of parallelism moved round in each lunation, by three equal ſmall wheels on the lunar arm, the interior one being faſt to a fixed tube, as we ſuppoſe, exhibits the phaſes for each day of the moon's age, which are indicated alſo on the cover, at ſome little diſtance from the horary circle. Above the ecliptic circle are erected a braſs ſemicircle for half the equator, the ſolſtitial colures, the ſummer tropic, and arctic circle, with the polar point; which appendages add to the appearance of the machine; and the works are admirably preſerved by a caſe, with glaſs both above and round the body of the machine, which is ſuperbly ornamented with chaſed work, in many figures reſembling the fore-part of a horſe, between each animal of the ecliptic ſigns; and our only ſurpriſe is, that ſo much money is expended with ſo little real effect. At each ſide of the handle is a braſs knob: when the right-hand one is drawn out, the ſecondaries of Jupiter and Saturn, as well as the rotation of Mars, ceaſe to move; and when the left-hand one is drawn in like manner, the ſuperior planets themſelves ſtop; but the earth and moon, with the inferior planets, move with the handle under all circumſtances.

The reader of this account may have remarked, that the numbers uſed in the *grand orrery*, (as it has been very properly called, if we ſurvey the exterior of it only,) has the numbers of the teeth in its wheels all *compoſite*, or ſuch as are diviſible by hand; and it is ſaid that the wheels were all divided and cut, before an engine was uſed in England, which is the manifeſt reaſon why great accuracy in theſe numbers was not attempted: for prime numbers would have produced thoſe difficulties in the execution, which the uſe of a perfect engine has now entirely removed.

Ferguſon's Orrery.—James Ferguſon invented various inſtruments from time to time for illuſtrating the phenomena of the ſolar ſyſtem, and his works are in every one's hands, which contain the drawings and deſcription of them; but that which is known by the name of Ferguſon's Orrery is the moſt accurate, and merits our notice in this place; it comprehends the motions of the Sun, Mercury, Venus, Earth, and Moon, and is particularly deſcribed both in the author's "Select Mechanical Exerciſes," and in his "Tables and Tracts," to which the reader is referred for the plates and deſcription of the mechaniſm, which is rendered ſufficiently intelligible. On examining the numbers of which the wheels have their teeth compoſed, we found that the author has attributed to them greater accuracy than they really poſſeſs, for which reaſon we ſhall ſubjoin the wheelwork, together with the value of each train, as well as the periods attributed to the machine by Ferguſon; from a compariſon of which it will appear how neceſſary it is to eſtimate the value of any train of wheelwork in expenſive machines by actual calculation, rather than take on credit the periods attributed to them by their author. It will be ſufficient for our preſent purpoſe to give the numbers of the wheels and pinions of each train, with the correſponding periods, in a table.

TABLE

TABLE of Ferguſon's Trains, with their correſponding Periods in Time.

Motions.	Wheelwork.	Periods. D.	H.	M.	S.
Earth's diurnal motion -	$\frac{25}{8} \times \frac{69}{7} \times \frac{83}{7}$	365	5	48	58.78
A lunation -	$\frac{30}{64} \times \frac{63}{1}$	29	12	45	0
Sun's rotation -	$\frac{25}{8} \times \frac{69}{7} \times \frac{64}{78}$	25	6	35	36
Revol. of Venus	$\frac{25}{8} \times \frac{69}{7} \times \frac{73}{10}$	224	20	47	8
Rev. of Mercury	$\frac{18}{28}$ of Venus + 1	87	23	47	24
Rot. of Venus -	$\frac{8}{74}$ of its revol.	24	22	31	8
Moon's node -	$\frac{56}{59}$	$18\frac{2}{3}$ years.			
Earth's parallelism	$\frac{40}{40} \times \frac{40}{40}$	1 revolution.			

Beſides theſe wheels and pinions there are others for ſubſidiary purpoſes, which do not enter into the calculations of the periods, and are therefore omitted in this brief account, which is intended only as an appendage to Ferguſon's own deſcription. The periods attributed by the author are as follow; *viz.*

	D.	H.	M.	S.
Earth's diurnal motion - -	365	5	48	57
A lunation - - -	29	12	45	0
Sun's rotation - - -	25	6	0	0
Revolution of Venus - -	224	17	0	0
Ditto of Mercury - - -	87	23	0	0
Rotation of Venus - -	24	8	0	0

It may be ſaid in favour of this ſtatement, that the deſcription is a popular one, and therefore ſufficiently accurate for ordinary readers; but when the author undertakes to appreciate the errors of his wheelwork, which he has done, a more correct report of the periods is indiſpenſable. The rotation of Venus, according to Bianchini's determination, which Ferguſon has here adopted, is no longer conſidered as the proper rotation. There is conſiderable ingenuity ſhewn in the contrivance for making the rotations of the handle agree with thoſe of the earth.

Mr. Benjamin Martin's Orrery, or Microcoſm.—In the ſecond volume of Benjamin Martin's "Mathematical Inſtitutions" (p. 479, et ſeq.) we meet with a detailed account of ſome aſtronomical mechaniſm which he propoſed to be attached to a clock, about the year 1764, under the name "Microcoſm," or little world; but we do not find that the plan was ever put into execution. It was not intended to be the regular repreſentative of all the ſolar ſyſtem, with the motions in their due places, but ſuch a repreſentation only as would exhibit the planetarium portion in one place of the clock, the tellurian in another, and the lunarium in a third; and, as it ſhould ſeem, a Jovian lunarium was intended to be occaſionally ſubſtituted for the planetarium, to go by the motion of the clock. The author, however, after having propoſed his plan, ſeems to have deſpaired of having any order given to make ſuch a piece of mechaniſm, chiefly from a conſideration, which is equally true in our own time; *viz.* that "by *arts* and *artiſts* we underſtand only *engraving*, *painting*, and *ſculpture*, and thoſe who practiſe them;" ſcientific mechaniſm being not uſually comprehended under thoſe terms, as being but little cultivated; and the more faſhionable ſtudies of chemiſtry and galvaniſm, we may add, at preſent engroſs the principal attention of the philoſophical world. But though the microcoſm was, perhaps, never conſtructed as an appendage to a clock, yet it laid the foundation of our more modern planetaria, tellurians, and lunaria, which conſtitute the orrery in three parts, as conſtructed by the workmen of Meſſrs. Adams, Jones, &c.; on which account we ſhall deſcribe the different portions ſeparately, and ſuggeſt ſuch obſervations to the reader as may enable him to appreciate their accuracy. For a deſcription of the planetarium portion, the reader, however, is requeſted to turn to the article PLANETARIUM, where our plan of arrangement has placed it as a ſeparate inſtrument.

The Tellurian Portion.—Tellurian is a word which owes its origin, we believe, to B. Martin, and which implies a detached portion of mechaniſm, calculated to repreſent the annual and diurnal motions of our earth (tellus) only, and as ſuch, was at firſt, as it ſtill continues to be, an appendage to the planetarium, and forming with it and the lunarium the common orrery: the principal requiſites for this inſtrument, or rather portion of an inſtrument, are a train of wheels for preſerving the conſtant parallelism of the earth's axis, on which, together with its proper inclination, depends the change of ſeaſons, and another train compoſed of an exact ratio between a ſolar day and a ſolar year, on which depends the continual alternate ſucceſſion of day and night. For the deſirable purpoſe of leſſening the number of wheels which would be required in two diſtinct trains, the inventor has very judiciouſly fixed upon two wheels which ſhall be common to both trains, *viz.* 365 and 59; the former of theſe, which is neceſſarily large, has no motion itſelf, but communicates a circular motion to the 59, by means of their teeth being connected, whilſt the latter is carried round it, by the annual bar, once in a year, and as theſe wheels are attached to the ſame ſtand which is uſed with the planetarium, the ſame handle and wheelwork which gives motion to the earth's radius vector there, will give motion to the annual bar here. A motion being once communicated to the wheel 59 in this manner, all the other motions of the wheelwork connected with this, and placed with it on the annual bar, will continue as long as the handle moves which actuates the annual bar. The trains made choice of are theſe; *viz.*

For the Earth's parallelism - $\frac{59}{365} \times \frac{62}{10} = \frac{3658}{3650}$ or 1.002192

Diurnal and annual train - - $\frac{59}{365} \times \frac{10}{20} \times \frac{8}{40} \times \frac{10}{59} = 365^{d}\ 0^{h}\ 0^{m}$

In the firſt of theſe trains the product of the numerators or driven wheels ſhould have been exactly equal to the product of the denominators or drivers, in order that one retrograde revolution of the laſt moving wheel of 62 might be effected in exactly one direct annual revolution of the bar; or, in other words, the ratio ſhould have been equal to *unity*, which it exceeds, and therefore the parallelism will not be conſtant, but will require a manual rectification as often as the error amounts to a ſenſible deviation. With reſpect to the other train, the value of which ought to have been $365\frac{1}{4}^{d}$,

$365\frac{1}{4}^d$, or rather $365^d\ 5^h\ 48^m\ 48^s$, the effect of its error is, that the diurnal motion, compared with the annual motion, loſes nearly a quarter of a day in every year, ſo that the horary index, if immediately connected with the tubed arbor of the laſt pinion of 10, and the annual index, are conſtantly at variance, and in the ſhort ſpace of four years, namely, on every biſſextile, this diſagreement amounts to a whole day. But the *quantum* of motion was not the only object of attention in the laſt, or diurnal pinion of 10, its *direction* alſo was to be attended to by the contriver, that the earth ſhould have its rotations from weſt to eaſt, otherwiſe they would not be natural; this, however, would not be the caſe without ſome additional wheel; for as the wheel of 59 revolves round the large wheel of 365 from weſt to eaſt along with the annual bar, and with it the wheel of 20 placed on the ſame arbor, the firſt pinion 10, and wheel 40, on the ſecond arbor, have their motion retrograde; then the third arbor with the pinion 8, and wheel 59, are again direct, and the laſt arbor, or tube, with its pinion 10, becomes in its turn retrograde; and if the earth had been immediately connected with this tube, its motion would conſequently have been retrograde too. The two wheels of each 59 might indeed have been omitted, without affecting the calculation, one being a multiplier, and the other a diviſor, and then there would have been one arbor fewer; but then the axis of the earth was to have an inclination, which it could not have if placed on the tube of the laſt pinion 10, two additional pinions, therefore, became neceſſary, one on the upper end of the tube, and the other on the retrograde bar of parallelism where the axis is fixed, on which the earth revolves; theſe two pinions are each 10, it being of no conſequence what they are, provided they be ſimilar; but hence ariſes a new motion, which the inventor probably did not ſuſpect, when he made his calculation for 365 days; for as the bar of parallelism revolves *backwards* once in a year, and carries the pinion connected with the earth's axis backwards along with it, whilſt its teeth are connected with the teeth of the central pinion on the tube, this pinion makes one retrograde revolution in a year *from this cauſe*, and brings the earth back again one entire revolution in that time, ſo that, in fact, the earth, by this mechaniſm, makes only 364 complete revolutions on its axis in each year, inſtead of 365, for which the calculation was made; hence, an horary index is altogether uſeleſs, if placed on the earth's axis; and if placed on the tube, which revolves 365 times, it would not correſpond with the earth's rotations by one day in a year; and this defect being found out, was probably the reaſon why no horary index is deſcribed as belonging to this inſtrument.

But there remains yet a further deduction of a day in the year, in this inſtrument, to be explained, which reduces the number to only 363, but which is not connected with, nor dependent upon, the diurnal train: this ariſes entirely from the retrograde motion of the annual bar of parallelism; it is a truth, perhaps not much, if at all, noticed by inſtrument-makers, though not the leſs true on that account, that provided the earth had no diurnal motion at all during its annual progreſs, the circumſtance of its axis being always parallel to itſelf, would produce juſt one day in a year, with this remarkable phenomenon, that the ſun would riſe, or appear to riſe, in the *weſt*, and ſet in the *eaſt*, which is juſt the reverſe of the ſun's apparent motion produced by the earth's rotation: this day, ariſing from the annual motion, would have added another day to the days in a year if the earth's rotation had been from eaſt to weſt, and what is now the number of ſidereal days, would then have been ſolar, without the addition of this one, that is to ſay, an inhabitant of any part of the earth would tranſit the meridian ſolar ray 367 times; for the real rotations of the earth would produce 366 tranſits, and one more would be derived from the annual gyration which preſerves the parallelism by preſenting every point of the earth ſucceſſively to the ſun in the courſe of the year. On the contrary, becauſe it happens that the earth's rotations are from weſt to eaſt, and the annual gyration from eaſt to weſt, in this caſe the *annual day*, as it may be called, is a deduction from the ſolar tranſits, which therefore are $366 - 1$, or 365, omitting the fraction; hence in every inſtrument which exhibits the diurnal and annual motions, and alſo the parallelism of the earth, the actual rotations of the earth produced by the train of wheelwork ſhould be 366, as in nature, ſeeing the bar of parallelism deducts one ſolar day in every year; but it has been ſhewn that the rotations of the earth, in the tellurian in queſtion, are actually only 364, ariſing from the whole operation of the diurnal train, and two additional pinions, from which we muſt further deduct one for the drawback of the annual gyration, which deduction leaves only 363 actual ſolar days exhibited by the mechaniſm. The following alteration would obviate theſe defects of two days' motion ariſing from decompoſition; let both the wheels of 59 be left out of the train; its value would not be affected thereby, but there would be only three arbors, including the tube, inſtead of four; the earth then would rotate 365 times the wrong way about, or from eaſt to weſt, by means of the train, and once more the *ſame way about*, in this caſe, by means of the ſecond pinion, on the bar of parallelism as it revolved round the central pinion of the ſame number fixed on the tube, which would make 366 rotations; add now a third pinion to the earth's axis, and it will revolve 366 times from weſt to eaſt, and the annual gyration will make the neceſſary deduction, but ſtill there would be a defect of $5^h\ 48^m\ 48^s$ in each year.

The Lunarium Portion.—Lunarium is alſo a word which we think occurs in the author before us for the firſt time; its import is an inſtrument which exhibits the motions of the moon (luna), or otherwiſe an appendage to another more comprehenſive inſtrument, in which it performs this office when attached. The principal motions of this ſecondary planet are, 1ſt, the monthly motion, which may be conſidered either as the period that begins and terminates with a ſtar, or with the ſun, the former of which is called the periodic revolution, and the latter the ſynodic revolution, or a lunation; 2dly, the anomaliſtic revolution, which is ſhorter than a lunation, but longer than a periodic revolution, by reaſon of the line of the apſides having a progreſſive motion in the ecliptic, which the moon has to overtake; and 3dly, a revolution in regard to the nodes, which is the ſhorteſt of all, by reaſon of the ſlow retrograde motion of the line connecting the nodes, which meets the moon in every lunation. Theſe three periods have each a ſeparate train of wheels, in each of which the common pair $\frac{59}{365}$, uſed in the tellurian, forms the firſt portion; the three trains, with their values in time, are theſe, *viz.*

		D.	H.	M.
Moon's ſynodic revolution	$\frac{59}{365} \times \frac{20}{20} \times \frac{10}{20}$	29	12	0
Moon's apogee	$\frac{59}{365} \times \frac{70}{10} \times \frac{78}{10}$	3221	9	36
Moon's nodes	$\frac{59}{365} \times \frac{18}{6} \times \frac{30}{6} \times \frac{48}{6}$	7080	0	0

The large wheel of 365 is here again a fixed wheel, round which

which all the other wheels are carried by the annual bar, as in the tellurian, which is taken from the ſtand, when the preſent mechaniſm is put on, and as the wheel 59 has its teeth in connection with the large wheel, it revolves the ſpace of one tooth in every day, as the year advances, and finiſhes its revolution in 59 days, $\frac{10}{20}$ or $\frac{1}{2}$ of which is $29^d\ 12^h\ 0^\circ$, the ſynodic revolution, in which the error is $44^m\ 3^s$ nearly, an error of too much magnitude to be overlooked by a mathematician, if he had been anxious for the accuracy of his inſtrument. The next train is calculated to make an elliptic ring, repreſenting the moon's orbit, advance through the 12 ſigns of the ecliptic in the period ſpecified, which, according to La Lande, ſhould have been 3231.35791 days, ſo that the error is nearly ten days in this period. The laſt train carries round an inclined circular plate or ring, moveable on an axis inſerted at the nodes, to ſhew the moon's variation of latitude; the retrograde period of this plate, according to La Lande, ſhould have been 6798.20337 days, the error therefore is ſtill more conſiderable than in the laſt motion, its amount being a ſpace in the ecliptic equal to 281.79663 days' motion.

From the examination which has here been detailed of Martin's planetary numbers, the reader, it is preſumed, will not think the inference unfair, if we aſſert that the various inaccuracies which have been pointed out, ſhew the propriety of abandoning theſe numbers in future, and of ſubſtituting others which ſhall exhibit the various motions more faithfully.

Orrery for the Motions of the Sun, Moon, Earth, and interior Planets, by the Rev. W. Pearſon.—During the time that Mr. Pearſon reſided at the city of Lincoln, he wiſhed to procure an orrery at a moderate expenſe, and conſtructed from numbers which might have ſome pretenſions to accuracy, but not being able to accompliſh his wiſh, after a correſpondence with an inſtrument-maker in London on the ſubject of his enquiry, he determined to try if he could not contrive an inſtrument himſelf to be made under his direction by an ordinary clock-maker. After ſome conſideration he deviſed the mode of calculation, which, under our article NUMBERS *Planetary*, we have called the *indirect method* of calculation, by which he ſoon aſcertained numbers ſuitable for his wheelwork. He found it convenient, however, to adopt the annual train of Ferguſon, which, at that time, he thought ſufficiently accurate; this train he tranſmuted into $\frac{14}{300} \times \frac{14}{46} \times \frac{16}{83} = 365^d\ 5^h\ 48^m\ 58^s$. The large wheel of 300 formed the plate that was graduated on its plane into a quadruple ſpiral of days, an ecliptic circle, and a declination circle, and was ſupported by claw feet, but not at its centre. The axis of pinion 16 had the arbor for the diurnal handle, and was carried along with the reſt of the train on bridges, under an oblong box that moved round the ſun in a year, and that contained the wheels of the moon and of the earth's paralleliſm at the remote end, and the wheels of Venus near the centre; to the under face of the annual box was made faſt a large wheel of 120, which drove the trains of Mercury and the Sun, ſupported by bridges under the large plate; the motions were taken by pinions above the plate, having their arbors paſſing down through it till they reſted on the cocks beneath; the laſt wheel of Mercury had a long tube which penetrated the ſun's ſtem and carried an arm at the top, which, by its mechaniſm, ſhewed both the equation of the centre, the variation of diſtance, and the heliocentric latitude, as ſeen in *fig.* 3. *Plate* IV. of *Planetary Machines*, and explained under the article EQUATION *Mechaniſm*. The arbor of the ſun's laſt wheel paſſed again through Mercury's tube, and gave the proper motion to his inclined axis by the medium of three ſimilar pinions, one on the ſaid arbor, one on the ſun's bearing piece, and one on his axis. As we have not given a drawing of this orrery, we ſhall not enter into a minute detail of the poſition of the different wheels and other parts, but ſubjoin a table of the trains and their correſponding values, which will give the reader a competent idea of its powers when carrying a three-inch globe with its furniture at $7\frac{1}{2}$ inches from the ſun, and the other planets at proportional diſtances, while Venus alſo moved in her inclined orbit by means of her arm having a joint at the ſun's ſtem, and reſting on an inclined graduated circle.

TABLE of the Trains &c.

		D.	H.	M.	S.
The Earth's wheels	$\frac{14}{300} \times \frac{14}{46} \times \frac{16}{83}$	365	5	48	58
Its parallelism ditto	$\frac{120}{100} \times \frac{100}{120} = \frac{1}{1}$, or one revolution.				
Moon's ſynodic do.	$\frac{14}{300} \times \frac{90}{21} \times \frac{38}{94}$	29	12	43	31
Moon's anomal. do.	$\frac{28}{30}$ of a lunation	27	13	28	37
Moon's nodes	$\frac{20}{102} \times \frac{121}{25}$	18^y	224	18	21	28
Trop. rev. of Venus	$1 + \frac{63}{97} \times \frac{40}{40} \times \frac{96}{39}$	224	16	42	7
Do. of Mercury -	$\frac{15}{120} \times \frac{79}{41}$	87	23	16	44
Sun's rotation -	$\frac{30}{120} \times \frac{27}{97}$	25	9	59	32

Three pinions of 15 for the earth's axis.
Three pinions of 8 for the ſun's axis.

Mercury's excentric motion $\frac{8}{25} \times \frac{25}{8} = \frac{1}{1}$ revol.

Three pinions of 30 for the moon's phaſes.

Theſe wheels were all put in motion by a common watch movement, by means of a pinion of 8 inſerted on the fuſee arbor, and driving a ratchet-wheel of 48 on the diurnal arbor, which, by means of the ratchet, turned without affecting the going of the watch during the time of lecturing. This was the ſmall orrery mentioned in Dr. Thomas Young's lectures, as being the moſt accurate of any he had examined, and certainly is more accurate than any that preceded it. Its rectifications and uſe will be underſtood from what will hereafter be ſaid, when other inſtruments have been deſcribed, which appear to merit a more particular deſcription by the aid of drawings.

The Orrery invented by Joſ. Prieſtley, eſq. of Bradford in Yorkſhire.—Mr. Prieſtley, a relative of Dr. Prieſtley, contrived and ſuperintended the conſtruction of an orrery in the year 1801, for Dr. Birbeck, who ſucceeded the late Dr. Garnett in the profeſſorſhip at Anderſon's univerſity, in Glaſgow, which orrery was made by Thomas Liſter, an induſtrious clockmaker of Hallifax, in the ſame county.

As we have been favoured with a deſcription of this inſtrument by the ingenious inventor, and alſo with a ſketch of the covering plates by the workman himſelf; we ſhall have little more to do in the account than to copy this deſcription, to examine the calculations adopted by the contriver,

contriver, and to make ſuch obſervations as have occurred in the examination.

The wheelwork, according to Mr. Prieſtley, is contained in a round box of braſs, thirty inches in diameter, and about four inches in depth; having the figures, repreſenting the ſigns of the zodiac, painted in enamel upon the ſide. The planets move in orbits at the exact proportional diſtances from the ſun, the mean diſtance of the earth being five inches, each orbit having its proper excentricity and inclination; and the periodic times, as well as the inequality of motion in each revolution, are nearly ſuch as are found by the lateſt obſervations.

The covering plates, which are painted blue, have narrow openings between them, through which paſs the ſtems which carry the planets: theſe openings repreſent the orbits; and their inclination to the ecliptic is produced by ledges raiſed round the openings. Adjoining theſe ledges are divided circles, on which the latitude, the nodes, and the apſides, are marked. The ball repreſenting the planet is fixed to a ſocket, which fits the ſtem, and reſting on the ledges, riſes and falls as the planet approaches or recedes from the north pole of the ecliptic.

The large gilt ball, repreſenting the ſun, moves round its axis, according to our author, in $25^d\ 15^h\ 16^m$, and the axis itſelf has the proper inclination and poſition given to it.

The orbits of Jupiter and Saturn extending beyond the circumference of the box, arms are neceſſarily uſed for theſe two planets. There are two ſeparate arms for Jupiter; one of which has wheelwork, that accurately exhibits his diurnal revolution, and the motions of his ſatellites in their reſpective orbits. Either arm may be put upon the two ſtrong wires that riſe out of the box, and move in an orbit left between the covering plates, concentric with Jupiter's, on the outſide of the orbit of Mars. When that arm, which ſhews the motions of the ſatellites, &c. is uſed, a bevel pinion is put on a ſquare axis paſſing from the wheelwork in the box, between the two ſtrong wires above-mentioned; this pinion acts in another, attached to a ſpindle paſſing through the hollow arm, and communicates motion to the train under the body of Jupiter.

The arm of Saturn, being very long, is ſupported by a ſtay, carrying a bar with two friction-wheels; which roll along the bottom moulding of the box. This arm, where it approaches the box, ſeparates into two branches, and is fixed to two ſtuds, that riſe above the covering plates. Theſe ſtuds are carried round along with a narrow rim, adjoining to the ecliptic and other circles deſcribed on the margin of the top of the box. This rim, not being in the plane of the box, occaſions the arm to riſe and fall during a revolution, cauſing the ball, repreſenting Saturn, to deſcribe an orbit, having a proper inclination to the plane of the ecliptic.

The ſtem ſupporting the ball and ring of Saturn iſſues out of a ſmall circular plate, divided into the ſigns and degrees of the ecliptic, and moveable on its centre at the extremity of the arm; this centre being perpendicularly under that of the ball. On this ſtem the ſatellites are moveable by the hand, and it has the proper inclination with reſpect to the plane of the ecliptic. By placing over the arm the ſame ſign and degree of this ſmall ecliptic that Saturn then occupies, the planes of the ring and of the orbits of the ſatellites will obtain their true poſitions.

The heliocentric places of the planets are ſhewn on an ecliptic circle, drawn on the outermoſt fixed rim of the top of the box: the year is pointed out by an index fixed to the arm of Saturn, and the day of the month is ſhewn on a circle adjoining to the earth's orbit. The proportional magnitudes of the planets, but not of the ſun, are nearly ſhewn in this orrery.

The Georgian planet and his ſyſtem of moons compoſe a ſeparate inſtrument, to be put on any convenient ſtand, and placed at the due diſtance from the ſun in the orrery. The centre of his orbit is at 4.54 inches from that of the ſun, in a line with $11^s\ 17^\circ\ 22'$. At this point a ſmall pin may be ſcrewed into the covering plates, and a ſtring, 96 inches long, ſtretched from them to meet another ſtring proceeding from the point under the ſun's centre, laid over the degree of the planet's heliocentric longitude, will give his true ſituation. The longitude is ſhewn on a ſilvered plate under this ſeparate ſyſtem for ſeveral years to come; and this plate, by means of the ecliptic circle engraved upon it, ſerves alſo to place the axis of the planet, and the plane of the orbits of his moons, in the right ſituation in the manner above deſcribed for Saturn.

The unequal motion of the planets in the different parts of their orbits has been attempted to be ſhewn; and the velocities in this orrery will be found to agree, nearly, with the Keplerian law of equal areas, deſcribed in equal times. Two methods have been employed for this purpoſe; for the inferior planets and Mars, that which is deſcribed as "*Mr. Joſeph Prieſtley's Contrivance*," under EQUATION, is employed; but the earth, having a ſyſtem of wheelwork to carry along with it, would not conveniently admit of the ſame contrivance; and Jupiter and Saturn being placed on arms, which extend beyond the box of the orrery, the ſame method could not be adopted for thoſe planets. In theſe three inſtances, the variation of motion in queſtion is obtained by an inequality among the teeth of the wheels, which carry theſe bodies round the ſun, the proper method of dividing or cutting which is deſcribed in the article already referred to.

With reſpect to the phenomena ariſing out of the motions of the earth, &c. the machinery admits of four changes; *viz.*

1. In ſhewing the general appearances of the ſolar ſyſtem, a ſmall ivory ball, proportioned to the ſize of the other planets, and a bead repreſenting the moon, are uſed: in this caſe the paralleliſm of the earth's axis and the moon's motion round the earth are ſhewn; but not the earth's diurnal motion.

2. The ball and bead above-mentioned being removed, an apparatus is put on in their place for ſhewing the apparent, ſuch as the direct, retrograde, and ſtationary, motions of the primary planets; and the geocentric place of any planet is ſhewn by an index on a ſmall ecliptic circle under the earth.

3. This apparatus is changed for a ſmall circular plate, the centre of which occupies the place of the earth, and its rim is divided into the points of the compaſs. This plate, which is intended to repreſent the rational horizon of the place, can be fixed to the inclination proper for the latitude of the ſpectator's ſituation, and its meridian line being brought to paſs through the ſun, and the hour index being ſet to 0 hours, the orrery is rectified for ſhewing, in the moſt natural manner, the phenomena and correſponding times of the riſing, ſouthing, and ſetting of the ſun and planets. By turning the winch ſlowly, and keeping the eye in the plane of the horizon circle, the planets will appear to aſcend above and deſcend below that circle exactly as they would do in nature, at the time for which the orrery is rectified. A thread fixed to the centre of this horizon, and ſtretched to any of the planets, will ſhew its bearing and the

the angle made by the thread and horizon, or angle of altitude, for the time pointed out by the hour index.

4. Laſtly, to the proper ſtems which riſe from the wheelwork within the box, are adapted a ſmall terreſtrial globe, and a ball repreſenting the moon: the globe has the annual and diurnal motions, and that by which the paralleliſm of its axis is maintained: the moon moves round the earth in an orbit properly inclined; having the retrograde motion of the nodes, and a motion on its axis to ſhew the phaſes. Behind the globe repreſenting the earth is placed a ſmall ſtem, carrying a circle of illumination to divide the enlightened from the other hemiſphere. This part of the apparatus, though ſufficiently large to ſhew the general phenomena reſpecting the moon, the viciſſitudes of the ſeaſons, and the different lengths of the ſucceſſive days and nights, does not interfere with the motions of the planets.

The wheelwork is ſo contrived, that one turn of the handle anſwers to 24 hours of mean ſolar time; when a quicker motion is required a change can be inſtantly made, ſo that one turn is equivalent to ten days: this latter motion will be found more convenient when the relative velocities of the planets round the ſun, the inequality of the motion of a planet in the different parts of its orbit, and the apparent motions as ſeen from the earth, or other place in the ſyſtem, are exhibited as objects of peculiar attention. When the planets are truly placed in their orbits for any given time, the wheelwork will preſerve, ſufficiently near, for many years paſt or to come, their proper ſituations.

To ſhew the time of the riſing, ſouthing, and ſetting of the heavenly bodies, a ſmall hour circle, with an index, is placed near the earth, and carried with it round the ſun.

This orrery was conſtructed with the deſign of its being placed on a ſtand, which would admit of its being inclined towards, or turned back from the audience, and at the ſame time of being moveable on an axis round its centre, ſo as to bring any part of the ecliptic in front. When the face of the orrery is inclined towards the company, the poſition, excentricity, &c. of the orbits, and the motions and magnitudes of the planets, are more conſpicuous; and the motion on the axis is uſeful for bringing the inſtrument into the moſt favourable point of view, during the deſcription of any particular phenomena; and when the planes of the orbits are turned out of a horizontal poſition, the handle may be inſerted into a hole made beneath the box, in which ſituation the lecturer's aſſiſtant may conveniently turn the handle, whilſt the lecturer is deſcribing the effects produced by the particular portions of the mechaniſm.

To demonſtrate in the moſt natural manner the phenomena of the apparent places, motions, &c. of the planets, as ſeen from the earth, proviſion is made among the wheelwork, for carrying a large radial rim, the centre of which coincides with that of the earth, during the revolution of the latter round the ſun; on the inſide of this rim is drawn, or intended to be drawn, the ecliptic with the conſtellations, or principal ſtars thereof that lie within 10° on each ſide of it. The apparatus for ſhewing the apparent motions of the planets, above deſcribed, is to be uſed along with this rim; when the wire paſſing through the centres of the earth and planets will ſhew, by means of a ſmall bead affixed to its extremity, the apparent place, and motion of the object among the ſtars of the zodiac, exactly as they would appear at the time to the eye of a ſpectator, viewing the ſame in the heavens from the ſurface of our globe.

The wheelwork conſiſts of the following trains; *viz.*

From the handle $\frac{55}{9} \times \frac{72}{10} \times \frac{83}{10} = 365.2$, that is, one turn *per* day very nearly; or by moving a ſlide the portion $\frac{55}{9}$ is diſcharged, and the train becomes $\frac{22}{36} \times \frac{72}{10} \times \frac{83}{10} =$ 36.52 turns in a year, or one turn in ten days very nearly.

The large wheel of 83 teeth revolves once in a year, and gives motion to the ſeveral wheels and pinions placed round it, which produce the periodical revolutions of the planets, as under; *viz.*

		D.	H.	M.	S.
Sun -	$\frac{9}{83} \times \frac{13}{18} = 12.76923$ {rotations *per annum*, or one, as it reſpects the Earth, in}	28	14	28	30
Mercury -	$\frac{8}{83} \times \frac{40}{16} = \frac{320}{1328}$, or $\frac{20}{83}$ of $365.^{d}24$ -	88	0	13	52
Venus -	$\frac{12}{83} \times \frac{102}{24} = \frac{1224}{1992}$, or $\frac{51}{83}$ of ditto -	224	10	11	23
Mars -	$\frac{12}{83} \times \frac{156}{12} = \frac{1876}{996}$, or $\frac{156}{83}$ of ditto -	686	11	24	15
Jupiter -	$\frac{48}{83} \times \frac{164}{8} = \frac{7874}{664}$, or $\frac{984}{83}$ of ditto -	4330	1	46	52
Saturn -	$\frac{88}{83} \times \frac{222}{8} = \frac{19536}{664}$, or $\frac{2442}{83}$ of ditto -	10745	23	25	57
Diurnal Motion	$\frac{10}{397} \times \frac{10}{46} \times \frac{12}{24} = 365.24$, or -	365	5	45	36
Paralleliſm -	$\frac{19}{235} \times \frac{47}{19} \times \frac{30}{6} = \frac{26790}{26790} =$ 1 year, or -	365	5	45	36
Lunation -	$\frac{19}{235}$ of 365.24 - - - -	29	1	43	15.6
Moon's Nodes	$\frac{56}{59}$ (eſtimated thus $\frac{56}{3}$) = $18\frac{2}{3}$ years -	6817	20	48	48

In

In this analyſis of the wheelwork and their powers, it is to be underſtood that the 83 is the ſame wheel in each train, and that the large wheel of 397, in the train of the diurnal motion, is fixed immoveably, but gives motion to the firſt pinion 10, which is carried round it by the annual motion: the laſt pinion 12 of this train has an axis which paſſes through the other ſockets, and communicates, by means of three ſmall equal wheels, a proper motion to the earth's axis.

The inventor ſays that the diurnal motion of the earth, and the motions of Jupiter's ſatellites, were not originally intended to make a part of this machinery; that is, it was intended to be ſimply a planetarium, but it was afterwards converted into an orrery. We entertained our doubts whether in this conſtruction of the train, that regulates the daily motion, the earth's motion on its axis would be uniformly ſteady, but in a ſecond communication from the author we learnt, that "by accurately proportioning the ſizes of the wheels and pinions, and uſing high numbers in this train, the ſmall globe is made to revolve with regularity, and without any inconvenient friction or ſtreſs on the teeth." For the moon's phaſes there is, moreover, a ſucceſſion of three equal wheels, the firſt made faſt to a central ſocket in the uſual way.

For the motions of Jupiter and his moons the following machinery is uſed. On the lower end of the ſquare axis, (paſſing from the wheelwork in the box between two ſhort wires,) ſtanding perpendicular to, and carried round with the wheel that produces Jupiter's revolution, is put a pinion of 10, which is driven againſt the 183 teeth cut in the inſide of the rim-like wheel, having 216 teeth on its outſide, which 216 teeth are adapted to the wheel of 72 teeth in the train of the handle. By theſe means the ſaid ſquare axis will move round by the train $\frac{55}{9} \times \frac{72}{10} \times \frac{216}{72} \times \frac{10}{183} = \frac{55}{9} \times \frac{216}{183} = \frac{55}{1} \times \frac{24}{183}$ $= 7\ \frac{39}{183}$, or 7.21918 days coming directly from the handle; but the pinion of 10 teeth is carried by Jupiter's arm $\frac{183}{10}$ or 18.3 revolutions backward in each period of Jupiter, each of which is equal to 7.21918 days; therefore, the whole drawback is 7.21918 × 18.3 = 132.114 days; hence we muſt ſay, as 4330.^{d}0741 : 132.^{d}114 : 7.^{d}21911 : 0.^{d}22026; this quantity taken from 7.^{d}21918 leaves 6.^{d}99892 for the true period of the arbor of pinion 10 to revolve in, as the firſt mover of the four pair of wheels and pinions for Jupiter's ſatellites. The motion of the arbor of the pinion 10 is tranſmitted to the common arbor of the drivers by the train $\frac{9}{66} \times \frac{88}{12} = \frac{792}{792}$, or unity; therefore the common vertical arbor turns in the ſame time as the one at the interior end, and the pinions of tranſmiſſion are put at the oppoſite ends of a long arbor paſſing through the middle of Jupiter's tubed arm, and act with each a contrate wheel of the numbers above ſtated,

The wheelwork of the four ſatellites of Jupiter, as well as of his diurnal motion, are theſe, with their annexed values, *viz.*

			D.	H.	M.	S.
Jupiter's wheels	$\frac{7}{118}$	of 6.99892	0	9	57	52
1. Satellite	$\frac{21}{87}$	of ditto	1	16	32	43
2. Ditto	$\frac{33}{65}$	of 6.99892	3	13	16	44
3. Ditto	$\frac{85}{83}$	of ditto	7	4	1	17
4. Ditto	$\frac{79}{33}$	of ditto	16	18	7	11

Of theſe numbers it may be obſerved that they are not ſo accurate as Roemer's, which take their motions from a period of ſeven days, which is very nearly alſo the period of the common arbor in this inſtrument that contains the drivers.

The new Orrery for equated Motions in three Parts, by the Rev. W. Pearſon.—After the planetarium, conſtructed at the Royal Inſtitution, had been finiſhed under Mr. Pearſon's ſuperintendance, he calculated numbers proper for a tellurian and lunarium to be combined into one inſtrument, as a neceſſary accompaniment, with a view to have it conſtructed for the uſe of the inſtitution; but circumſtances prevented ſuch meaſure being put in execution, or even being propoſed to the managers. In the year 1805, however, the plan was put into the hands of Fidler, who completed the inſtrument in a very perfect manner for the inventor himſelf. In the following year the ſame gentleman added both the planetarium portion, and the ſatellite portion, to be ſucceſſively applied to the ſame inlaid mahogany ſtand, which three portions, accurately made, and ſeparately applied, conſtitute an orrery the moſt perfect, perhaps, in its operations, of all the machines that have hitherto been invented in any country. As the PLANETARIUM and SATELLITE portions of this ſuperb orrery form ſeparate inſtruments individually, we ſhall, agreeably to our propoſed plan, defer the deſcription of both theſe till we arrive at the articles themſelves, under their appropriate titles; and ſhall confine ourſelves in this place to a detail of the parts that conſtitute the firſt portion, or tellurian and lunarium united; which portion may, according to our definition, be conſidered in itſelf as the moſt eſſential feature of the orrery: but in the mean time, it may be proper to mention, that the motions of the primary planets, in the planetarium or ſecond portion, move in excentric orbits with their variable diſtances and velocities, making equal areas in equal times in their exact periodical times; and that the third portion, containing the ſyſtem of Jupiter and his moons, together with the proper motion of the earth, produces the periodic times with a degree of accuracy never before accompliſhed by mechanical means. The three portions are applied, or may be applied, in ſucceſſion, to the ſame ornamental ſtand, as the ſubject may demand, or they may have each a ſeparate ſtand.

An inſtrument capable of repreſenting with extreme accuracy, and on a large ſcale, all the motions of the earth and the moon at the ſame time, had long been a deſideratum in the philoſophical world. For while the attention of the mathematical inſtrument-maker was occupied by ſtudying portability and neatneſs in conſtructing the tellurian and lunarium, as detached portions, to be applied ſucceſſively to the ſame ſtand, the utility of the inſtrument, ſo diſunited, became circumſcribed; inaſmuch, as all the phenomena, which depend upon the motions of the earth and moon, taken conjointly, are inexplicable by it. It muſt be allowed, indeed, that from obſerving the modern tellurian in motion, a ſpectator might form a competent idea of the natural ſucceſſion of the ſeaſons, and of day and night; likewiſe, by attending to the lunarium he might ſee the cauſe of eclipſes and lunar aſpects explained; but, as to

the *time when*, and the *places* on the globe *where* any eclipſe will be viſible; and alſo as to the ſolution of all the numerous variety of problems which have a reference to *time* and *place*, the modern inſtruments on ſale leave us entirely to the wide field of conjecture. The tellurian and lunarium, as heretofore conſtructed, not only explain by *halves*, effects, which the *mind* muſt afterwards combine, but have their wheelwork ſo imperfectly calculated and arranged, that even thoſe partial repreſentations, which they profeſs to exhibit, are very inaccurate: for inſtance, all the tellurians, which we have had occaſion to examine, in the different ſhops of London, make the ſolar year to conſiſt of an *entire day* too much, or elſe too little; to ſay nothing of the fractional portion of a day, which ſome of them omit to take into the calculation, notwithſtanding a ſupplementary day ought to be provided for in every leap year.

Theſe, and other inaccuracies, both in the lunar motions, and in the earth's annual courſe, (by the latter of which the ſummer and winter half-years are improperly made to conſiſt of an equal number of days,) pointed out the neceſſity of having a new inſtrument conſtructed, which might correct the errors, and ſupply the defects of the very imperfect ones, which had heretofore been uſed in ſeminaries and public lecture-rooms.

The inſtrument, which we here offer to the public notice, is, we underſtand, the reſult of much contrivance, and of great labour in aſcertaining, by numerous calculations, the moſt accurate poſſible numbers for its wheelwork. The hours which had been ſpent, in analyſing the various inſtruments which were made during the laſt century, produced a conviction; that though much had been attempted and profeſſed to be done by different men on the preſent ſubject; yet no real improvement, ſince the days of Huygens, had actually been effected in inſtruments for explaining celeſtial phenomena; unleſs, indeed, the ſcenic effect produced by the Eidouranion be conſidered as an improvement. Aſtronomers without mechanical ſkill, and artiſts without ſufficient ſcience, alike laboured under difficulties, in the contrivance and execution of ſuch an inſtrument as may be deemed perfect of its kind; and how far the pretenſions of the contriver of this machine for uniting the two requiſite qualifications may be well founded, will beſt be proved by an examination of the inſtrument itſelf.

Plate V. of *Planetary Machines* repreſents a perſpective view of the firſt portion of the orrery on a reduced ſcale, as ſeen when put together.

A B is a circular table or ſtand of mahogany two and a half feet in diameter, to which is faſtened immoveably the large contrate wheel of 269 teeth. C D is a bar of braſs, which revolves round the centre piece of cylindrical braſs E upon a ſhoulder, and reſts alſo near the extremity of the table on the braſs friction-wheel above A, and is called the *annual* bar, by reaſon of its being carried once round in a year; at the remote end of this bar, beyond C, is fixed the annual index, that points out in a quadruple ſpiral, drawn on a braſs rim on the ſurface of the table, the days of the month in the firſt, ſecond, third, or fourth ſpiral line, accordingly as the year may be leap year, or the firſt, ſecond, &c. after; and alſo indicates the ſun's place in the ecliptic and his declination in two interior circles, as well as his mean anomaly and correſponding equation of the centre; all which graduations are engraved along with the ſigns of the ecliptic. The ſmall contrate wheel of 62, which appears in an inverted poſition above E, is alſo fixed faſt to the central braſs piece; but all the other parts of the mechaniſm are carried by the annual bar, either above it, or below it; and the wheels borne by it are put into motion, as it goes round, partly by means of the pinion of 10, hidden with the long arbor under the annual bar, being connected with the fixed wheel of 269, and partly by the pinion of 8 on the long arbor above it, being acted upon by the immoveable wheel of 62.

The train of wheels, which carries the annual bar round, and alſo gives the daily motion to the earth, is compoſed of the exact ratio between a day and a ſolar year, and conſiſts of the following numbers, *viz.* $\frac{10}{269} \times \frac{10}{26} \times \frac{18}{94} = \frac{1800}{657436}$ which ratio inverted is equal to $365^d\ 5^h\ 48^m\ 48^s$.

This train is agreeable to Lalande's determination of the ſolar year *exactly*, there being not an error of ſo much as even the fractional portion of a ſecond in a year: hence, when the machine has been made to revolve for the ſpace of a million years, it will require no rectification of this train, it being as accurate as the tables themſelves, whence the ſun's place is taken from the Nautical Almanac. The manner in which the foregoing train is arranged, to produce its effect, is thus; the large wheel of 269, which is immoveably fixed to the table, gives motion to the firſt pinion of 10, which is concealed on the interior end of the long horizontal ſteel arbor placed under, and parallel to the annual bar, whilſt this bar moves forwards; then the contrate wheel of 26 being faſt upon the ſame arbor, which is lowered from its place above A to be ſeen, revolves in the ſame time, and actuates the ſecond pinion of 10, placed on the firſt perpendicular arbor, and ſupported by a cock F beneath the annual bar, on which perpendicular arbor is alſo fixed the wheel of 94 above the annual bar and under the bridge G, into which the upper end of this arbor is pivoted. Laſtly, the wheel of 94 drives the ſmall wheel of 18 (not ſeen) round in an exact day; which laſt wheel is ſoldered to the lower extremity of a long tube almoſt ſix inches long, that bears alſo the ſmall wheel of 40 on its ſuperior end, for the purpoſe of communicating motion to a ſimilar wheel, placed on the earth's axis, by the help of an intermediate wheel; which three wheels have ſimilar numbers of teeth and dimenſions; the long tube is ſupported by, and revolves upon, a long poliſhed piece of ſteel, ſcrewed home into the annual bar, and kept faſt to its place by a tapped nut below the bar, which perpendicular piece of ſteel, or ſtem, is turned in a lathe in ſuch a way that the two extremities of the revolving tube move freely upon it without ſhake, but with as little friction as poſſible, for which purpoſes the whole length of the ſtem is a little diminiſhed in diameter, except at the two ends, on which the extremities of the tube revolve. By this portion of the mechaniſm the *exact* proportion is preſerved between a ſolar day and a ſolar or tropical year.

The next portion is that part of the mechaniſm by which the earth's axis is preſerved parallel to itſelf in every part of its annual orbit; this conſiſts of two contrate wheels of ſimilar dimenſions, each containing 62 teeth, one placed with the teeth downwards faſt to the central ſtem above E, and the other revolving above the bridge G with its teeth uppermoſt, that its motion may be in a retrograde direction, and round a long tube made faſt to the bridge, which is interpoſed between the tube of wheel 18, and the tube on which the wheel 62 is faſtened, ſo that the fixed intermediate tube of the bridge keeps the other two tubes from touching one another, and ſerves as a ſtem for that of wheel 62. The motion is communicated, from the fixed to the revolving wheel, by means of two ſimilar pinions of 8, which may be of any number of teeth, placed at oppoſite ends of the long horizontal ſteel arbor, which revolves parallel to and above the annual bar, by means of the connection that the interior

pinion

pinion has with the fixed wheel, while the annual bar is in motion: the horizontal arbor is pivoted into the bridge H at one end, and into a cock K at the other. On the ſuperior end of this third tube, or tube of 62, is placed, in an adjuſtable manner, the circular rim I, of nine inches diameter, on which an ecliptic circle is engraven, (and on which a circle of declination might be engraven alſo, inſtead of that on the table): to this rim is attached, by ſcrews, the bearing piece L, which ſupports a terreſtrial globe of nine inches diameter, fitted up with a quadrant, and moveable meridian and horizon circles to be adapted to any longitude and latitude. Again, by means of the retrograde motion of the ecliptic circle I of one revolution, for every direct revolution of the annual bar, the axis of the earth is made to point always to the ſame individual diſtant point in every part of its annual orbit; or, in other words, it preſerves its paralleliſm perpetually; on which circumſtance, together with the inclination of the axis, the viciſſitude of the ſeaſons depends.

Now, whilſt the little ecliptic circle revolves backwards once in a year, it carries the earth along with it, and therefore preſents every part of the globe ſucceſſively to the ſun's rays, by which operation, provided the earth had no rotation on its axis, one night and one day only would be the lot of its inhabitants in every year, and the ſun would appear to riſe in the weſt, and ſet in the eaſt, which phenomenon would really take place in nature, if the earth's motion on its axis were ſtayed, (of which circumſtance, we believe, aſtronomers have taken no notice.) To this phenomenon, however, it is owing, that an exact rotation of the earth, as it regards a fixed point in the heavens, conſtitutes not a ſolar, but a ſidereal day, the duration of which is only $23^d\ 56^m\ 3.^s43$ ſolar time, the difference between which and a ſolar day amounts to an entire day in every ſolar year; hence in every 365,242 natural days, the earth makes 366,242 rotations on its axis, which would be ſo many natural days, if the paralleliſm of the earth's axis were not preſerved, which paralleliſm effects a deduction of one day in a ſolar year, in the way that has been deſcribed. The queſtion then ariſes, how the additional rotation is given to the earth's axis by the mechaniſm before us? The effect is this; *viz.* while the central wheel of 40, under the end of the antarctic circle, revolves 365,242 times, the piece L, carried by the ſmall ecliptic plate, carries the next wheel of 40, or intermediate wheel, *round* the central wheel in a retrograde direction, while their teeth are in action, which circuit would give the intermediate wheel juſt one revolution, provided the central wheel had no motion at all; but the intermediate wheel receives by communication 365,242 revolutions from the central wheel, independently of the additional one in conſequence of the circuit; therefore, the total number of revolutions which it makes in a retrograde direction are 366,242, which it communicates to the third wheel of 40 placed on the earth's axis, without either addition or diminution; conſequently, the earth makes exactly 366,242 rotations in 365,242 natural days. It is to a want of attention to this circumſtance, that muſt be attributed the inaccuracy of our modern tellurians, for either an addition or ſubtraction, occaſioned by a compound motion derived from the annual circuit, has rendered them uſeleſs as to all the purpoſes connected with particular deductions. By this conſtruction of the inſtrument, both ſolar and ſidereal time are indicated on the ſame dial-plate M, placed on the top of the tube that revolves in twenty-four hours, by means of the two hands O and P, the former of which is placed on a fixed ſtem of ſteel, round which the tube revolves, and the latter, P, is carried in a retrograde direction by the ecliptic circle once round in every year, ſo as to meet any particular hour on the horary plate $3^m\ 56.^s57$ ſooner than it did on the preceding day; ſo that, if the two hands be put to the ſame hour on the day on which the ſun enters Aries, the ſpace on the horary plate contained between the two hands, on any day in the year, will be the difference between ſolar and ſidereal time, or, what is the ſame thing, the ſun's mean right aſcenſion for that day converted into time. In all problems relating to ſolar time, the hand O muſt be conſulted. N is a circular braſs plate, ſupported by the upper end of the tube which belongs to the bridge H, and has the days of the moon's age engraven on it, together with the times of her meridian paſſage, and the equations of the tides on each day of her age, according to her diſtance from the apogee. Q is the terminator for the circle of illumination, adjuſtable to any height; and at right angles to this terminator, a lens, R, is ſuſpended to produce a ſolar ray on the ſurface of the globe, adjuſted to the height of the centre of the earth, which points out where the ſun is vertical on any given day, as alſo the variation of declination, and a variety of other phenomena in a very ſtriking manner.

Another eſſential requiſite peculiar to this inſtrument is, that it makes ſummer as it is in nature, nearly eight days longer (from the vernal to the autumnal equinox), than winter (from the autumnal to the vernal.) This is effected, without any additional mechaniſm, by the cutting of the teeth of the large contrate wheel of 269, in ſuch a manner, that there is a gradual increaſe in the ſize of each ſucceſſive tooth through one ſemicircle, and a correſponding decreaſe in thoſe of the other, ſo that there are $5\frac{3}{4}$ths more teeth in one ſemicircle of the wheel than in the other, and conſequently a proportionate number of days motion of the earth, counted on the ſolar dial-plate, during its continuance in the aphelion or ſummer ſemicircle of its orbit; than in its perihelion or winter ſemicircle of its orbit. See EQUATION.

Again, as the cauſe of the variation of the ſeaſons is generally explained ſeparately from the cauſe of alternate days and nights, a contrivance is requiſite to detach the diurnal from the annual motion of the earth, for otherwiſe the ſlowneſs of the annual motion would be unfavourable to an explanation of the phenomena which depend upon the paralleliſm only; for this reaſon the firſt pinion 10, on the horizontal arbor under the annual bar, which is pivoted into the concealed cock and under the arm, over the teeth of wheel 269, is capable of being detached at pleaſure from the large wheel, by turning the tapped and milled nut S above the annual bar, which draws up the ſquared bearing piece of the cock, into a ſquare ſocket faſtened to the annual bar, and along with it the end of the arbor, ſufficiently high for the pinion to clear the wheel; by which elevation all the motions which depend upon the great wheel of 269 are allowed to ſtop.

Having now detailed the particulars of the tellurian portion of the inſtrument, the lunarian portion demands our attention. Let it, however, be premiſed, that to conſtitute a perfect inſtrument, the motions of all the different parts of the mechaniſm, however accurately calculated, ingeniouſly arranged, and exactly proportioned, with a view both to comparative dimenſions and ſtrength, muſt commence as nearly as poſſible at the ſame time; otherwiſe the indications on the different graduated faces and circles will not exactly correſpond with one another: for inſtance, we have ſeen the moon, in ſome inſtruments of great value, or rather we ſhould ſay of great price, not commencing its motion round the earth, on turning the handle, until the earth has made upwards of a complete rotation on its axis. Such effect was therefore to be guarded againſt, by taking the communication of motion for the moon, not from a ſlowly moving annual

nual wheel, as is uſually done, but from the ſame wheel from which the earth derives its motion, which firſt moving wheel ought to be nearly equally diſtant from all the laſt moving wheels in the inſtrument, in order that the reſulting incipient motions may be *contemporary;* to effect this deſirable purpoſe, the wheel of 94, belonging to the earth's train, is cut both at the edge, and alſo as a contrate wheel, to be driven by the unſeen wheel of 18, placed on the arbor of the handle T, and revolving in 24 hours, for the ſame reaſon that the other wheel of 18 on the long tube revolves in this time; by this ſituation of the handle, all the different trains are coupled together, and begin to move at the ſame inſtant; and what appears to be moreover an advantage, the lecturer may very conveniently turn the handle for himſelf, whilſt he accompanies the earth in its annual circuit, and reads the diviſions on the different faces. The horary circle, U, contains alſo the ſeven days of the week, indicated by a ſecond hand revolving in $\frac{18}{18} \times \frac{56}{8}$ of a day, which is an exact week.

The train of wheels for producing the moon's ſynodic revolution, or monthly motion, being connected alike with the annual and diurnal ends of the earth's train, on account of having its motion communicated from the middle of the earth's train, may be differently denominated, and may have its value aſcertained, either as the improper fraction of a day, or as the proper fraction of a year, it being ſo peculiarly circumſtanced, for the ſake of gaining *immediate* motion, as to take in either half of the earth's train, as a conſtituent portion of its own, whereby there becomes a ſaving in the number of wheels, without a diminution of accuracy in the value of the train: for if we begin to calculate from the large wheel of 269, and conſider it as conſtituting the firſt wheel of the lunar train, we ſhall have $\frac{10}{269} \times \frac{43}{13} \times \frac{48}{73}$ of $365.^{d}242 = 29^{d}\ 12^{h}\ 44^{m}\ 3^{s}.28765$; but if we begin at the earth's axis with the wheel of 18, we ſhall have $\frac{94}{18} \times \frac{26}{10} \times \frac{43}{13} \times \frac{48}{73}$ of a day $= 29^{d}\ 12^{h}\ 44^{m}\ 3^{s}.28765$, as before, four extra wheels being all that we have occaſion to introduce, in addition to the earth's train, to effect a degree of accuracy in the ſynodic revolution, which far exceeds any thing that has been done before, in this or any other country, with the ſame number of wheels; the error being little more than a quarter of a ſecond in an entire month.

The arrangement is thus: on the long arbor under the annual bar, and nearly at the remote end, is fixed a driving pinion or ſmall wheel of 13 to actuate the contrate wheel of 43 reſting on the cock V, ſhewn a little below its true place, on the perpendicular arbor of which wheel is alſo pinned faſt the wheel under the cock W, of 73, which wheel drives the tubed wheel of 48 round in the time already ſpecified; the tube of the wheel of 48 revolves round the fixed tube of the bridge H, and ſuſtains on its upper end the braſs bar X X, which carries the moon round the earth, and ſupports the mechaniſm belonging to her: this monthly bar may be adjuſted to any ſituation by the clamping piece ſeen near the handle T. The moon's latitude is not regulated by an inclined plate, commonly called the nodes' plate, which, for a globe of nine inches diameter, would have been too large and heavy for the wheelwork; but by a forked lever of ſteel, on which the moon's ſtem reſts, that is raiſed and lowered alternately during the period with reſpect to the nodes; this motion is derived from the lunation thus; a lunation is to an anomaliſtic revolution of the moon, as 777 are to 716, very nearly, which numbers are capable of forming the train $\frac{16}{74} \times \frac{179}{42}$ of a lunation, which will be a period of $27^{d}\ 5^{h}\ 5^{m}\ 36^{s}9$, in which the error is $+ 1.''3$ only. The action of this train is thus; the wheel 74 is fixed faſt on the tube of bridge H, and has therefore no motion, while the monthly arm, X X, is carried round it; the pinion 16 lies on the upper face of this arm, inſerted faſt on the upper pivot of a vertical arbor, the lower end of which reſts on the two-fold cock, ſeen above U, but which, together with the ſaid pinion, is nearly concealed by plate N lying over them; on the under ſide of the monthly arm, and on the ſame vertical arbor, completely concealed, is the ſmall wheel 42 driving the contrate wheel 179, on the horizontal arbor, that lies parallel to, and under the arm: the rim of this contrate wheel is wide enough to admit of the diviſions for ſhewing the moon's latitude, by the edge of the arm uſed as an index, and its poſterior face has an excentric plate, reſembling a circle flattened on one ſide, and ſurrounded by an edge-bar of the ſame ſhape, which edge-bar taking the fork of the ſteel lever Y, gives it the alternate motion which raiſes and lowers the moon's ſtem. A ſcrew in the cock Z, under the arm, preſſes againſt the horizontal arbor of wheel 179, and allows its teeth to come out of action when ſcrewed back, ſo that the graduated rim may be brought to adjuſtment for latitude, in any ſituation of the arm, and ſcrewing in puts the teeth again into action. The moon's argument of latitude, or diſtance from the node, is alſo marked on the rim of 179; and the fulcrum of the lever is at one-third of its length from the forked end, in the cock Z.

Laſtly, the mechaniſm for the moon's anomaliſtic revolution, or the time in which ſhe performs all her variations of diſtance from the earth, and on which her grand equation depends, remains yet to be explained. By a peculiarity in the conſtruction of this inſtrument, there is not an anomaliſtic plate, deriving its motion from an annual wheel, and indicating when the moon *ought* to approach to and recede from the earth, as is uſual in inſtruments where the anomaliſtic mechaniſm is introduced; but the *moon herſelf* actually moves *in an excentric orbit,* in the proper anomaliſtic period, and at the ſame time preſerves the due inclination of her orbit, which two requiſites have perhaps never before been combined by any mechanical contrivance.

The motion is derived from the ſynodic revolution thus; a wheel of 64 is fixed faſt on the top of the tube of bridge H, round which the moon's arm revolves, whilſt the wheel of 67 has a connection with the teeth of 64; the conſequence is, that the wheel of 67 is made to revolve, and with it the wheel of 46, which is attached to it; this laſt wheel ought to drive the wheel of 41, which is the laſt in the train, and which carries the moon alternately nearer to and farther from the earth, by means of a cranked ſtem, but they are neceſſarily too diſtant to act together, where the earth is on ſo large a ſcale as nine inches, the communication is therefore made by an horizontal arbor, which has a pinion at each end of ſimilar numbers, which conſtruction requires the wheels 46 and 41 to be both of them contrate; the effective train, therefore, is $\frac{67}{64} \times \frac{41}{46} = \frac{2747}{2944}$ of 29.5306 days, or the lunation of the wheelwork $= 27^{d}\ 13^{h}\ 18^{m}\ 32^{s}$, during which period the deviation from the truth amounts to only $1.''9499$ of time.

The ſtem, *a*, of the crank, *a b c d*, is ſquare, and paſſes through the ſocket of wheel 41, which is round without and ſquare within, and pivoted into the cock *e*, and lunar arm

X. This ſtem riſes and falls, as has been deſcribed, and carries the moon, reſting on the crank, along with it: this alternate riſing and falling of the moon in every revolution, with reſpect to the nodes, at the ſame time that ſhe departs from or approaches to the earth, once in every anomaliſtic revolution, by the motion of the crank, produces an orbit as nearly as may be like the real orbit of the moon, not only with reſpect to ſhape and poſition, but to acceleration and retardation alſo; for if the bend of the crank, meaſured from the ſtem to the moon's ſtem, be made to bear the ſame proportion to the mean diſtance of the moon from the earth, that *twice* the excentricity of the lunar orbit does to its radius, then the crank piece, *b*, will repreſent the whole equation of the centre, and will be alternately additive and ſubtractive, as in nature. Taking *twice* the excentricity, it muſt be granted, will render the lunar orbit too excentric for its diſtance from the earth, but when it is conſidered that the earth and moon are conſtructed on a large ſcale, the *diſtances* with reſpect to each other, and alſo with reſpect to the ſun, cannot poſſibly be preſerved, without making the annual bar immenſely long, therefore the objection on this ſcore vaniſhes.

Over the cock, *e*, is fixed a circular face to indicate the moon's diſtances and equations dependent upon them, by the help of the revolving hand *f*, which is placed on the upper extremity of the arbor of wheel 41, and which revolves in an anomaliſtic revolution, without riſing and falling with the ſtem of the crank.

The hand *i*, carried by the lunar arm, indicates the moon's age, meridian paſſage, tides, &c. on the fixed plate N.

From this account in detail of all the ſeparate parts of the inſtrument in queſtion, and of their application, it is preſumed that any artiſt, accuſtomed to wheelwork, may, without difficulty, proceed in the conſtruction, particularly as the order, in which the parts are deſcribed, is alſo the order in which they muſt be made and put together. The dimenſions have been purpoſely avoided, leſt a confuſion ſhould take place in the deſcription; and that they may be more conveniently referred to, a table of them is annexed to the end of this account, for the uſe of the workman.

It would enlarge our account too much, to introduce in this place particular directions for dividing the circles on the various faces of the plates; and would imply, beſides, a knowledge of the application of aſtronomical tables in the reader, in which few, comparatively ſpeaking, are converſant. We ſhall, therefore, paſs over the neceſſary directions in this place, as being worthy of a ſeparate notice, and as requiring appropriate drawings. It falls, however, within the province of the preſent account to ſay a few words reſpecting the method of dividing the quadruple ſpiral, in ſuch a way that each line may contain $365\frac{1}{4}$ ſpaces, in order to take in the 29th of February every fourth year. To effect this condition, the ſpiral muſt begin at noon of the 1ſt day of March, civil time, and end on the laſt of February; and alſo the day ſpaces muſt be proportioned to the velocity of the earth's motion in its annual circuit, which, we have ſeen, is either increaſing or decreaſing in every part of the circle round the ſun, in conſequence of the unequal teeth of the large wheel of 269. Here the ſkilful mathematician and the unlettered artiſt would probably find themſelves equally at a loſs how to ſet about a buſineſs apparently ſo complex. The ſpiral, however, being once drawn, which requires but little mathematical knowledge, (and ſtill leſs practice in mechanics, provided a beam-compaſs be at hand,) the buſineſs is perfectly ſimple and eaſy; for the inſtrument *will divide its own ſpaces* in the beſt poſſible manner: becauſe, as there are 365.242 turns of the handle for one revolution of the annual bar, all that is neceſſary, after having adjuſted a ſtraight edge to the index end of the annual bar, is, firſt, to turn the handle, and then make a dividing mark on the firſt ſpiral; then another turn, and another mark, ſucceſſively, until four years are gone through; care being taken to mark, by a long line, each 5, 10, 15, &c. of each month; and that the aphelion point of the large wheel, when the pinion is acting with it, be diametrically oppoſite to the degree in the ecliptic, where the ſun's apogee is, which at preſent is at $9\frac{1}{3}^{\circ}$ of Cancer.

Hence the inſtrument itſelf is the beſt poſſible machine for dividing the day ſpaces, both for expedition and accuracy; for, beſides the quickneſs with which the operation may be performed, if there ſhould happen to be a large or a ſmall tooth in the large wheel, from any cauſe, which tooth would accelerate or retard the annual motion, this mode of dividing will always *accommodate* the day ſpaces to the ſize of the teeth oppoſite them, without the intention, or even knowledge, of the perſon who divides; and as the ſame wheelwork muſt indicate which divided, there is the greateſt probability of the day ſpaces completely anſwering their intention, which could not be ſo well expected from any other mode of diviſion. An inſtrument made from this plan, well executed in its parts, and properly adjuſted, will work the various problems, adapted for the terreſtrial globe, by the mere turning of the handle, and that in the moſt natural way. The globe will be in reality what the new mounted globe only profeſſes to be; and, what is of no ſmall advantage to the learner, the *reaſon* will appear for drawing all the imaginary circles, which are uſually drawn on the ſurface of the globe, and which are generally taken for granted to be neceſſary, without a reaſon being aſſigned. In ſhort, the inſtrument will combine all the uſes of the terreſtrial globe, the tellurian, the lunarian, and the eclipſarian; and its operations will extend not only to explain and illuſtrate, but to calculate and foretell, without any limit of years to come, phenomena which require both great ſkill and perſeverance to predict by the help of aſtronomical tables. Laſtly, to the above-deſcribed inſtrument an apparatus is added, to illuſtrate the tides; and the ſun, or, inſtead thereof, an Argand's lamp, with a darkening cover, and convex glaſs, to make the rays of light fall parallel on the globe, is placed on the annual bar, and turns round the common centre of gravity between it and the earth. Likewiſe, a ſmall lamp is occaſionally carried by a lever attached to the moon's ſtem, at the inner end of which lever a lens is adjuſted, which throws a central lunar ray on the ſurface of the earth, as the ſun's lens does the ſolar light; by means of which luminous points travelling over the revolving globe, not only ſolar and lunar eclipſes, and the countries to which they are viſible, may be eaſily explained, but the riſing, ſetting, and culminating of either body will appear with the correſponding times on the reſpective graduated circles, for altitudes, azimuths, and amplitudes: in ſhort, all the phenomena, ariſing out of the contemporary motions of the earth and moon, will be exhibited by this machine as they happen in nature, particularly when ſmall pullies, for keeping the moon's lamp pointing properly to the earth, are duly applied during the revolution of the crank.

The pinions on the long arbors, as are alſo the wheels of 62, are optional.

The improved Orrery for mean Motions, contrived by the Rev. W. Pearſon.—We have already ſaid that a *grand orrery* is a machine which repreſents by wheelwork the motions of all the primary planets, and alſo of the moon and Jupiter's ſatellites, together with the diurnal motion, in combination with the annual motion of the earth: in fact, it unites the ſeveral properties of a tellurian lunarium, planetarium, and Jovian inſtrument in one machine, and is the moſt comprehenſive piece of mechaniſm, for explaining the ſolar ſyſtem, that has yet been invented, inaſmuch as that it exhibits each planetary body moving in its own orbit, while the whole ſyſtem is in motion together. After our author had ſucceeded in conſtructing a ſuperb orrery, for equated motions in three parts, from the moſt elaborate calculations, and on a ſcale of magnitude that is admirably ſuited for explaining different portions of the ſyſtem in diſtinct lectures, or leſſons, the firſt of which portions we have already deſcribed; he conceived a plan of uniting all the different detached portions into one machine, on a ſmaller ſcale indeed, but retaining all the eſſential motions, without the equations, that he had before repreſented in ſeparate portions with the equations, which combination of all the mean motions had never before been effected, even with tolerable accuracy, notwithſtanding the great expenſe that had been incurred in the conſtruction of huge machines, that profeſſed much more than they could perform, and that had brought the utility of planetary mechaniſm into diſrepute. The orrery we are now going to deſcribe, was not only calculated and planned by Mr. Pearſon, but completely conſtructed by Fidler under his direction, and from his plans and ſections, in the ſhort ſpace of two months, during the paſt ſpring (1813), and is found to anſwer the expectation of its contriver in its fulleſt extent. The outline of the plan was, to reject all unneceſſary expenſe ariſing out of bulk or complexity of conſtruction, but yet to retain all the variety of mean motions, that a full illuſtration of the ſyſtem demands in a lecture room; hence portability, ſimplicity, accuracy, ſtrength, and neatneſs, are the characteriſtic features of the machine; and conſidering the great variety of problems that may be ſolved by it in the moſt natural manner, by the aid of an equation table, the expenſe is by no means conſiderable. The purchaſe comes within the reach of every reſpectable maſter of an academy, which was the object the author had in view; and as he has himſelf ſet the example, in an eſtabliſhment of the firſt conſequence, it is preſumed that a minute detail of his labours may tend to benefit the riſing generation. It would have carried the inventor beyond the limits of his plan, if he had atempted to exhibit any other than *mean* motions, except in the caſe of the moon, whoſe exact place in the heavens is an object of importance in navigation, as well as in the explanation of eclipſes: neither would it have been conſiſtent with his views, to have aimed at *extreme* accuracy in all the periods, (particularly of the four newly diſcovered planets, which may want further correction in the lapſe of a few years,) but to unite ſimplicity with ſuch a degree of accuracy, that, while the motions are uniformly ſmooth and ſteady, no ſenſible error may ariſe in any of the periods for a century forwards or back: indeed, more than half the periods, particularly the moſt intereſting, are, notwithſtanding, rendered nearly as accurate as the periods collected from the aſtronomical tables themſelves, as will be ſeen in the ſubjoined table of errors. In order to convey to the reader a clear inſight into the different contrivances of this orrery, as well as to give him an idea of its external appearance, we have given two plates of it, VII. and VIII. of *Planetary Machines*; one explaining the internal ſtructure of the acting parts in combination, as well as explicative of the parts that act out of the caſe; and the other repreſenting a perſpective view of its external aſpect. The box A A B B, which contains the different trains of wheelwork, is cylindrical, 12 inches in diameter and three deep, ſupported by a pillar and three claw feet, ſeen in *Plate* VII., all of braſs neatly laquered; the frame C C, in *Plate* VIII., which contains the trains, is ſcrewed into this box, through four little pillars, two of which are ſeen at C and C, and may be taken out at pleaſure, after the circular cover is removed, which is alſo kept down by ſcrews; but the radii vectores, or arms of the planets, muſt firſt be taken off, with the appendages hereafter to be deſcribed. When the frame is taken out of the cylindrical box, and held in an horizontal poſition level with the eye, its ſection will appear as repreſented in the lower part of *Plate* VII., except that ſome of the wheels connected with the earth's train are diſplayed in *figs.* 2 and 3, for the purpoſe of being brought into view. The wheels are laid down in their due proportions, and of half their dimenſions, ſo that they may be copied without difficulty by any ordinary inſtrument-maker, who may be diſpoſed to adopt the conſtruction, and who, like Fidler, poſſeſſes the means of having the requiſite number of teeth cut in each of the wheels. It may not be improper to mention here, that this part of the work can be done by Fayrer, of Red-Lion ſtreet, Pentonville, in the beſt manner, by the famous

famous engine which we deſcribed, (ſee CUTTING-*Engine*,) as the invention of the late Rehé, and alſo that the expenſe of having all the wheels ſo cut is not very conſiderable. We will begin our detail at the diurnal handle near A, which is inſerted into a hole in the ſide of the braſs box, and takes the ſquared end of the horizontal arbor, which revolves in an exact ſolar day, and is pivoted into the double cock H; on the interior end of this arbor is fixed a bevel wheel of 24 teeth, driving another ſimilar wheel of 24 fixed above it, on the ſuperior end of the vertical arbor F, under the dotted cock C, which vertical arbor, therefore, revolves alſo in a ſolar day: on the lower end of this diurnal and vertical arbor is a pinion of 15, let down through a hole made in the plate C C, till the lower end of the arbor reſts on a little cock ſeen ſcrewed to the under ſide of the ſaid plate: this plate, C C, carries the annual train underneath it, and the reſt of the wheelwork above it; the pinion of 15, above referred to, drives the wheel 120, to which is fixed a pinion of 23, ſeen the loweſt, and driving the wheel 61, to which wheel is again made faſt, above it, the pinion 14, to drive the larger or annual wheel 241 round in a ſolar year, which it does with great accuracy, the whole train $\frac{120}{15} \times \frac{61}{23} \times \frac{241}{14} = 58804\frac{}{161}$, being equivalent to the period $365^{d}\ 5^{h}\ 48^{m}\ 49.^{s}192128$.

This train is repreſented as having the arbors in a ſtraight line, in order that their connection may be ſeen and underſtood, but in reality they are placed round the centre of the box, and occupy 240° of a circle, as may be ſeen in the calliper laid down in *fig.* 3. of *Plate* VIII., which we have inſerted for the uſe of the inſtrument-maker, who might not otherwiſe underſtand the proper poſition for theſe wheels. The wheel of 120, under the plate C C, is faſt to an arbor that turns between the dotted cock M, and the upper face of the plate, but projects through it to receive the wheel 120 and its pinion 23 below, to which they are pinned on a common tube; and the period in which this arbor revolves is eight days, namely, $\frac{120}{15}$: above the plate, and on this ſame arbor of eight days, is a wheel of 80, as ſeen in the detached *fig.* 2, (taken from the front of the centre of the box,) driving the wheel 70 in ſeven days; the arbor of this laſt wheel is pivoted into the plate C C, below, and into a cock not ſeen above, and its projecting end carries the weekly hand above the cover of the box; in like manner the projecting arbor F, which we have called the diurnal arbor, carries the hour index, both which are ſeen in the perſpective drawing in *Plate* VIII. The wheel 61, already noticed as one of the annual train, has its teeth connected with another pinion of 23, hid under the plate, but ſeen ſideways in the detached *fig.* 3, which gives motion to a third pinion, of the ſame number of teeth, placed on the vertical arbor, working in the dotted cock, which arbor, therefore, turns alſo in eight days, like the firſt pinion of 23; on this vertical arbor is a bevel wheel of 32, ſeen clearly in *fig.* 3, turning another of ſimilar ſhape on the horizontal arbor with 28 teeth, which arbor, therefore, alſo turns in ſeven days, and anſwers to the index on the cover of the box, already called the week-hand. The uſe of this ſecond horizontal arbor, or arbor of a week, which is repreſented as ſhortened, and without its cocks, is to receive the ſame handle whenever a quick motion is required to be given to the planets, after the diurnal motion of the earth is ſtayed, which is effected thus; the wheel of 61, under the plate C C, is not ſupported by this plate immediately, but turns on a pin or ſtud inſerted into a long bar of braſs L L, ſeen endwiſe in *fig.* 1. but lengthwiſe in *fig.* 3, which turns on a ſcrew under the plate near the centre of the annual wheel, juſt enough to detach the teeth of this wheel from the pinion of 23 on the arbor of wheel 120 (*figs.* 1 and 2.) when required: as the centre of motion of this bar, L L, is near the centre of the large annual wheel 241, the pinion of 14, on the ſame arbor with wheel 61, does not quit its connection with the ſaid annual wheel, but revolves a little way round it with their teeth in action, while the bar in queſtion is moved ſufficiently to detach wheel 61 as before ſtated: at the outward end of the ſaid bar, L L, is fixed the dotted cock of *fig.* 3, and alſo the unſeen cocks of the horizontal arbor for the weekly handle; theſe therefore, together with the bar, will move to the right and left the ſpace of about a quarter of an inch, taken at the exterior end of the arbor. By this contrivance the wheel 61 can be made to have a connection with both the diurnal and annual motions, or only with the latter, as occaſion may require; but when the diurnal motion is required, the handle will not enter the ſecond hole in the ſide of the box to take the weekly arbor, now turned aſide a little, which handle in that caſe is not wanted. The moveable bar, L L, has a hole tapped in its lower face, and a ſcrew with a milled head aſcends through the bottom of the box, in which it has a little play, to allow for the motion of the bar, which bar it then fixes underneath the box, in either the attached or detached ſituation of wheel 61. The utility of this contrivance will appear more clearly hereafter. The third arbor that appears above the box is the annual arbor of wheel 241, which carries the third or yearly hand; and the calliper is ſo contrived, that the three arbors for the hands form an equilateral triangle round the centre of the box, for the ſake of uniformity of appearance. In the centre of the plate, C C, is ſcrewed faſt a rod of ſteel, D D, perfectly perpendicular, upwards of nine inches long, and ſomewhat more than a quarter of an inch in diameter, into the top of which the ſun's ſtem is ſcrewed, and round which thirteen concentric tubes are placed, twelve of which revolve within one another; and the bore of the laſt is an inch and a quarter. From the top of the outermoſt to the top of the innermoſt tube is a length of five inches and three quarters, conſtituting twelve ſteps up the fruſtum of a cone, as ſeen in *Plate* VII.; theſe tubes have each a wheel fixed to its lower end, which wheels make them revolve, together with their attached arms and appendages, in their reſpective periods. We come now to deſcribe how theſe tubes have their motions communicated to them and their periods regulated.

The arbor, E E, of the annual wheel 241 revolves once in a ſolar year between the large plate C C, and the dotted bridge K, not entirely ſeen, which keeps it perpendicular: on this arbor are borne fifteen wheels and pinions, of which the four uppermoſt and the four undermoſt, ſhewn in ſection, revolve looſely in pairs pinned together reſpectively, and the ſeven intermediate ones, repreſented with teeth, are made faſt to one another, and alſo to the arbor, and conſequently revolve together in the ſpace of a ſolar or tropical year. In this conſtruction ſeven of the planets have their revolutions produced by each one pair of wheels, the numbers of ſix of which conſtitute ſo many improper fractions of a year, thoſe for the earth having like numbers to expreſs unity, or one year; but the two inferior and two remoteſt planets have each a train of four wheels, for the ſake of greater accuracy in the periods, than ſimple pairs are capable of producing in a practical form; to theſe the annual arbor performs the office of an upright ſtud, or long pin, round which they may revolve, each pair in a ſeparate ſtate, as their reſpective coadjutors direct; ſo that the conſtruction is of a mixed nature, conſiſting partly of ſimple ratios, or pairs of wheels,

like that of the common planetarium, and partly of trains derived from compound fractions; and retains much of the ſimplicity of the cheapeſt inſtruments, while it poſſeſſes the accuracy of the moſt expenſive. We might have begun with the longeſt tube, or loweſt wheels, and have proceeded in the order of their ſucceſſion, till we had explained the whole of the motions as they occur, but that the two interior planets derive their motions through the medium of each other, firſt from the Earth to Venus, and then from Venus to Mercury; ſo that we muſt neceſſarily begin from the motion of the earth, which takes that of the annual arbor unaltered, its wheels, one faſt on the arbor, and the other on the tube, being each 85, by which is meant having each 85 teeth, and the period we have ſeen is $365^d\ 5^h\ 48^m\ 49^s$, very nearly. Under the wheel 85 on the earth's tube, but above the bridge, S, with the fixed tube, is ſcrewed faſt a wheel of 113, driving its fellow of 63 round the annual arbor, to which is made faſt another driver of 58, which actuates a wheel of 64, made faſt to the tube of Venus under the bridge, the value of which train is $\frac{63}{113} \times \frac{64}{58}$ of a ſolar year, or $224^d\ 16^h\ 41^m\ 53^s$; again to this laſt wheel on Venus' tube is made faſt the wheel 78 of Mercury's train, which impels its fellow 97 round the annual bar, below the looſe pair of Venus, and has a wheel of 108 faſt to it, which again drives the wheel 34 on Mercury's tube in $\frac{97}{78} \times \frac{34}{108}$ of Venus's period, or in $87^d\ 23^h\ 14^m\ 37^s$. It is of importance that the periods of theſe two planets be correct, becauſe an error in either of them would accumulate in the inverſe ratio of the length of thoſe periods, which, being both comparatively ſhort, would ſoon render the error ſenſible by ſuch accumulation. The motion of the diurnal arbor comes next above the annual wheel of 85, in order to be tranſmitted along the annual bar to the axis of the earth, carried at its remote end; but this motion is modified in a way that will be explained by and by: it is thus communicated; a wheel of 50 is made faſt to the vertical diurnal arbor, that impels another of 100 fixed on the tube that next ſurrounds the annual tube already deſcribed: this latter wheel of 100, with its tube, therefore revolves in the ſpace of two days, which is all the notice we ſhall take of it at preſent: above this comes the pair of wheels for the revolution of Mars, *viz.* $\frac{79}{42}$, the 42 faſt on the annual arbor, and the 79 attached to the tube, the value of which ſimple fraction of a year is $687^d\ 0^h\ 4^m\ 38^s$.

Next to the tube of Mars comes that of Veſta, with 29 faſt on the arbor driving 106 on the tube in $1335^d\ 0^h\ 33^m\ 32^s$; after that 31 on the arbor drives 135 with the tube of Juno round in $1590^d\ 13^h\ 37^m\ 32^s$; and over theſe wheels a common pair, $\frac{138}{30}$, carry both Pallas and Ceres round in $1680^d\ 2^h\ 44^m\ 27^s$, by means of the 30, attached to the revolving arbor, impelling the 138 attached to their common tube. The pair of wheels which ſucceed the new planets before Jupiter's wheels come, are $\frac{55}{70}$, the 70 fixed on the vertical arbor of ſeven days, ſeen detached in *fig.* 2, and the 55 driven by it made faſt to the tube, which by theſe means revolves in $5\frac{1}{2}$ days for the purpoſe of communicating motion to Jupiter's moons, in the manner we ſhall preſently deſcribe.

Above this tube of $5\frac{1}{2}$ days revolves Jupiter's in $\frac{166}{14}$ of a year, or in $4330^d\ 17^h\ 30^m\ 1^s$, the 14 on the annual arbor giving motion to 166 with the tube upon it, and this is the laſt of the ſeven ſimple pairs.

The motion of Saturn is derived from Jupiter's period in this manner, like that of Venus from the Earth; the wheel of 53 is attached to Jupiter's 166, and revolves with it, driving 50 round the annual arbor looſely, while 46 is pinned to it, which in its turn drives the wheel 121 made faſt to Saturn's tube in the period of $10746^d\ 21^h\ 18^m\ 25^s$, or $\frac{50}{53} \times \frac{121}{46}$ of Jupiter's; and laſtly, the train of Georgian takes its motion from the tube of Saturn in a ſimilar manner; the wheel 86 is fixed on the tubed wheel 121 of Saturn, and actuates the wheels 46 and 28 pinned together round the arbor, uſed as a ſtem, and the latter of them again urges the wheel 149 on Georgian's tube in $\frac{46}{86} \times \frac{149}{28}$ of Saturn's period, or in $30589^d\ 8^h\ 32^m\ 25^s$.

Thus twenty-eight wheels and pinions are employed to give the revolutions of the eleven primary planets, as taken from the annual arbor, which wheelwork alone would ſuffice to make an accurate planetarium by a ſimilar application, without the other mechaniſm. The wheels for giving the ſun's motion on his axis from Mercury, might have been added to the above deſcribed wheelwork, but it was judged better to omit them for the ſake of ſimplicity and cheapneſs, eſpecially as the motion of the ſolar ſpots, when they happen to occur, is the only phenomenon to be exhibited by ſuch motion, which can eaſily be conceived from turning round the ſtem by which the ſun is ſupported.

We return now to the diurnal motion of the earth and the periods of the ſecondaries, as exhibited in this machine, which form very intereſting portions of the ſyſtem. We have already traced the communication of motion from the diurnal handle to a tube of two days' period, next above the annual tube, but not aſcending ſo high by one ſtep, while that of the bridge aſcends a ſtep above. Though the earth's arm is only $7\frac{1}{2}$ inches long from the centre of the ſun to that of the earth, yet it contains, in miniature, all the apparatus of the earth and moon, ſomewhat differently modified, that we have deſcribed as conſtituting the firſt portion of the orrery in three parts: the variations in the conſtruction demand, notwithſtanding, that we ſhould give, in this place alſo, a detail of the numbers employed, and the mode of their application, to produce a like effect by mechaniſm more portable. It will not, however, be neceſſary to dwell ſo minutely on the uſes of the different parts, as it would have been, if this arm had been deſcribed before the other inſtrument. The earth's annual arm, denoted by the letters *a b*, is a flat bar of braſs, made firm by an edge-bar fixed above it, and having a croſs-piece, *c d*, at its remote end, (ſeen in *fig.* 4. and partially in *Plate* VIII.) extending $1\frac{3}{4}$ from its centre one way, and $2\frac{3}{4}$ the other, to carry ſome of the wheels and other appendages, that Mars may avoid them in his orbit as the earth paſſes him: a ſlit tube, with a ſurrounding clamping piece and ſcrew, is attached to the upper face of the bar, by means of which it is ſecured to the upper end of the tube of the annual wheel 85, by which it is carried round in a ſolar year; but along with this arm, and immediately under it, a contrate wheel of 96, with its teeth pointing downwards, and having a ſimilar ſhort ſlit tube and clamping piece, is puſhed upon the end of the tube of two days' period, to which it is clamped

clamped faſt, while its teeth are in connection with thoſe of a pinion of 8 under the ſaid arm; but great care is neceſſary, before the final clampings, that the pinion's teeth be put at a proper acting depth into thoſe of the wheel: this pinion has an arbor extending the whole length nearly of the arm, and parallel to it, but is carried by two cocks beneath it, in a way ſimilar to the horizontal arbor ſeen above the arm: the remote end of this lower horizontal arbor has a ſimilar pinion attached to it, which drives another wheel of 48 teeth, alſo contrate, but with its teeth pointing upwards to alter the direction of motion; the time of a revolution of this latter wheel is, therefore, one day, or half the time of a revolution of 96 that revolves in two days: the diurnal wheel of 48, juſt deſcribed, has a ſolid arbor, ſupported by a bridge under the croſs-piece of the arm at its lower pivot, and by the annual arm, which it penetrates at $\frac{5}{8}$ of an inch above: this arbor ſtands in a poſition perpendicular to the arm, and is three inches long, and about $\frac{2}{10}$ in diameter. On the upper end of this arbor is fixed, ſimply by friction, a ſmall wheel of 36, impelling a ſimilar one, a little bevelled, on the earth's axis, which, by this communication of motion, makes the earth revolve in one day when the annual motion of the arm is ſtayed; but when the annual motion is uſed along with the diurnal, the pinion revolves round the contrate wheel of 96, and gives the motion of 96 teeth or two days to the 48, which by this combination of two motions makes $367\frac{1}{4}$ inſtead of $365\frac{1}{4}$ revolutions in the year. A novice in calculations of this nature would pronounce this to be an error of two days in the year, as theſe two days' motion are tranſmitted without alteration to the earth's axis; but the truth is, the effect of this combination was not only foreſeen, but taken into the calculation of the annual train as a compenſation for a deduction of two days' motion, which the earth experiences from a combination, in another place, of an oppoſite nature, but to the ſame amount. The contrivance for keeping the earth's axis parallel to itſelf in all parts of its orbit, which we ſhall ſoon deſcribe, gives the earth a retrograde motion annually, by which one rotation in the year is deducted from thoſe given by the train; and as the two wheels of 36 are connected during this retrograde motion, the one that is fixed on the earth's axis makes a retrograde revolution in the ſame period, by being carried round the other during the lapſe of the year, thereby making a ſecond deduction of a day in the year: theſe two days ſubtracted from the $367\frac{1}{4}$, produced in the way above deſcribed, leave the number of days in a year $365\frac{1}{4}$, as in nature. It is to a want of a compenſation of this ſort that the old orreries and tellurians are moſt of them of little value in the ſolution of problems where time is concerned, as we have already had occaſion to notice. It is but doing juſtice to the ingenuity of Janvier, the French mechanic, to aſcribe to him the contrivance of this ingenious mode of compenſation, which is very convenient when the diurnal handle is in a ſtationary ſituation, remote from the annual bar, as in the machine before us. Indeed, without ſome ſuch contrivance, the diurnal motion of the earth, and alſo of the handle, could not have been perfectly effected. The retrograde annual motion, for keeping the earth's axis parallel always, is derived from the contrate wheel of 62, placed by a clamping piece over the annual bar on the fixed tube of the bridge, with its teeth downwards ſo as to catch the teeth of the pinion of 8 above the edge-bar of the annual arm. The axis of this pinion is, in fact, ſupported at both ends by projections made in the edge-bar itſelf, inſtead of the two cocks; and a ſimilar pinion at its remote end gives motion to another contrate wheel of 62, with its teeth turned up, on account of the backward direction of its motion. The tube of this laſt wheel, ſeen detached in *fig.* 4, ſurrounds the diurnal vertical arbor, and ſupports the bearing piece P, in *fig.* 1, on which the earth's axis reſts, which axis will come out of the bearing piece when the pin with a circular head is drawn out of the ſide of the ſocket carried by this bearing piece; for a circular groove turned on the earth's axis, within the ſocket, allows the pin to paſs at one ſide of it along the groove, by which pin it is kept in its place, and is yet at liberty to revolve. The ſmall ecliptic circle O, for eſtimating the geocentric places of the moon and planets, reſts alſo on this annual tube of retrogradation, or of paralleliſm, by means of which the ſigns marked on it are kept parallel to the larger circle of ſigns ſurrounding the ſun. The lunation is derived from the annual wheel of paralleliſm, as is alſo the period of the nodes, thus; an annual wheel of 107, beſt ſeen in *fig.* 4, is made faſt to the 62, and, partaking of its motion, drives a pinion of 12, through the medium of a pinion of 15, which only changes the direction of motion, and the arbor of the pinion 15, which is a tube revolving on a ſtud at the end of the croſs-piece *c d*, carries on its upper end the wheel 86, which makes another wheel of 62 revolve, with its tube, in a proper direction, in a period of $\frac{12}{107} \times \frac{62}{86}$ of a year, or in $29^d\ 12^h\ 44^m\ 1.^s2$, in which train the error is little more than one ſecond *per* month in defect: in like manner, the train for the period of the nodes is $\frac{24}{62} \times \frac{76}{31}$ of a year, or 18 ſolar years, 23 days, 14 hours, and 49 minutes: 62 is the annual wheel, the 24 and 31 are pinned together, and revolve on a tube round a ſtud on the longer part of the croſs-piece *c d*, and the 76 bears, on the upper end of its tube, the inclined circle, marked *nodes*, graduated for the moon's latitude, on which the moon's ſquared ſtem is ſupported as it moves forward in its orbit. The anomaliſtic revolution of the moon is taken from the lunation, and the train, contained in the monthly ſmall frame, for giving the principal equation and variation of diſtance, is $\frac{67}{64} \times \frac{46}{41}$ of a lunation, or $27^d\ 13^h\ 18^m\ 32^s$, as in the larger machine before deſcribed. Before we take leave of the earth's arm, we think it right juſt to mention, that by reaſon of the compenſation in the diurnal motion of the earth, neither ſolar nor ſidereal time can be indicated on the arm itſelf; but we ſhall preſently ſee, that theſe are both indicated by the ſame hand, on two ſeparate faces, upon the cover of the box, where the reading is more convenient to the lecturer, while he turns the diurnal handle. It may be alſo requiſite to mention here, that the equations of the moon's centre are inſerted on the ſmall plate R at the remote end of the monthly frame; and alſo that the fixed rim Q, that has the moon's age marked on it, and which is croſſed out for lightneſs, is placed on the ſtationary tube carried by the cock T, that is ſeen between 62, the contrate wheel of paralleliſm, and 62, the lunation wheel next above. The furniture of the earth, which is a three-inch globe, is an horizon circle, a meridian circle, both adjuſtable, a quadrant of altitude adapted to the meridian circle, all graduated, an arc of illumination, and a ſolar lens U, for converging the light of the lamp, placed in the ſun's place occaſionally, into a focal point on the ſurface of the globe, which point, being luminous, ſhews the place of a vertrical ray at all times, and in all poſitions of the globe, and affords the moſt natural as well as moſt eaſy means of ſolving all the variety of problems in which the ſun is concerned. Immediately under the earth's arm a circular plate, N, is

clamped to the top of the ſtationary tube, on which are engraved a quadruple ſpiral graduated into day ſpaces in ſuch a way, that February has 29 days every fourth year; and within this is an ecliptic circle correſponding to the ſun's *mean* place on the reſpective days of the year, with a graduated circle within that to ſhew the equation of the ſun's centre, by which his mean place is immediately converted into his true or apparent place, by addition or ſubtraction, as the caſe happens to be. The aphelion points of all the planetary orbits are likewiſe marked within the ecliptic, which aſſiſt in computing the mean anomaly of any planet at any time; from which the equation of its centre may alſo be aſcertained and applied by the help of the proper tables calculated for this purpoſe. In the ſame manner, the place of the aſcending node of each planet might be inſerted, from which the heliocentric latitude might be eaſily deduced in problems, where great nicety is required. Indeed, exerciſes of this ſort would render familiar the application of the tables themſelves for finding the places, as given in the Nautical Almanac, and White's Ephemeris, without the aſſiſtance of thoſe helps. The end of the annual arm is prolonged acroſs this circular plate, and receives an index piece, V, in the form of a cock, that carries a ſilken thread ſtretched long enough to reach over all the divided circles, as well as the ſpiral, which thread at once indicates the day of the month in leap year, or any of the three following years, the ſun's mean place in the ecliptic, and the correſponding equation, additive or ſubſtractive, as the caſe may require. To the under face of this plate the contrate wheel of 62 for the earth's parallelism is ſcrewed faſt, and is thus attached to the fixed tube. As it was found convenient to make the earth's diſtance from the ſun ſeven inches and a half, to allow for the introduction of a three-inch terreſtrial globe to be put on, inſtead of the ſmall ivory ball, when problems are to be ſolved by it, this diſtance became the ſtandard by which the other diſtances were to be aſcertained. As far as Mars, incluſive, the proportional diſtances are preſerved; but beyond Mars certain proportional parts were neceſſarily adopted, inſtead of the whole diſtances, which in Saturn would have been 73 inches, and in Georgian 144. The following table contains the ſcale of diſtances which appeared to be, on the whole, moſt deſirable to fix upon for the reſpective lengths of the arms, that revolve with the planetary balls in this machine; and thoſe of Saturn and Georgian are made of tubes that ſlide within one another for the ſake of lightneſs, as well as of packing.

Table of Diſtances from the Sun.

Mercury	2.89 inches.	
Venus	5.45	
Earth	7.5	
Mars	11.45	
Veſta	13.4	*viz.* $\frac{7}{8}$ of 15.3
Juno	15.9	$\frac{4}{5}$ of 19.9
Ceres and Pallas	each 16.6	$\frac{4}{5}$ of 20.7
Jupiter	19.6	$\frac{1}{2}$ of 39.2
Saturn	21.9	$\frac{3}{10}$ of 73
Georgian	24.0	$\frac{1}{6}$ of 144

In order that an exact idea may be formed of the real proportional diſtances of Veſta and the planets beyond, as compared with that of the earth, ſix holes are drilled and tapped along the earth's arm, at the ſame proportional diſtances from the ſun, that the ſcale of this table requires, into any one of which holes the ſtem of the ſmall ivory ball may be ſcrewed; from which holes the reſpective planets muſt be ſuppoſed to be viewed, to gain the geocentric places reſpectively. For inſtance, if the geocentric place of Mars be required at any time, firſt allow for the equation of the centre from the table made for this purpoſe, by turning the planetary ball forward or back from its mean place, by a joint made for this purpoſe at the inſertion of the upright wire at the remote end of the arm, the quantity may be eſtimated by the ecliptic circle, which ſtands in a convenient ſituation for referring the places to: this being done, ſtretch a ſilken thread, from the earth's ſtem, ſcrewed into the fourth hole from the ſun in the earth's arm, till it lays over the centre of Mars' ball; then a ſecond thread drawn parallel to this, either from the earth, or from the ſun, as may be moſt convenient, will cut the geocentric place of the planet in the ſmall or large ecliptic circle, whichever be uſed. This uſe of the parallel threads anſwers the ſame purpoſe as placing an ecliptic circle in a parallel ſituation round the hole where the earth's ſtem is inſerted for rendering the two given diſtances exactly proportionable. This contrivance affords the means of working problems connected with the geocentric appearances, as well as if the arms had been all lengthened into due proportion; for when the geocentric places are aſcertained, the upright wires, by being turned on their centres of motion, will bring the planets into the aſcertained geocentric places, without moving the arms of mean motion out of rectification: for Saturn and Georgian, the tubes afford the means of doing this by turning one within another.

We come now to explain the mechaniſm connected with, and carried by, Jupiter's arm, which we have ſeen is 19.6 inches long: it will be recollected that we have traced the tranſmiſſion of motion from the ſeven days' arbor to a tube of $5\frac{1}{2}$ days, revolving next within Jupiter's tube: upon the upper end of this tube of $5\frac{1}{2}$ days, a contrate wheel of 60 is clamped with the teeth pointing down towards Jupiter's arm, with which it comes in contact: this arm is a long tube, and admits an arbor of the ſame length within it, which, conſequently, is not ſeen, except where the arm is diſunited: this long horizontal arbor has a pinion of 8 at each end of it, one of which is impelled by the ſaid wheel of 60, which deſcends through a notch made in the upper ſide of the arm or tube, till it catches the pinion; and the other drives a ſimilar wheel of 60 at the remote end of the tube, where a notch is made under the tube, through which the teeth of the wheel, pointing upwards, catch the teeth of this pinion. Now it is evident, from the ſimilar numbers, that if Jupiter's arm had no motion, this laſt contrate wheel of 60 would revolve in $5\frac{1}{2}$ days, as the other 60 does; but the motion of the arm round the ſun alters this period a little, which alteration muſt be aſcertained, before we explain the mechaniſm of the ſatellites, which derive their motions from this altered period. As the firſt pinion of 8 revolves round the firſt wheel 60 in Jupiter's period, it is made to revolve $\frac{60}{8}$, or $7\frac{1}{2}$ times in this period oftener than it would have done in a fixed poſition. Again, the ſecond pinion of 8, which may be conſidered as the ſame pinion prolonged within the tube, gives its $7\frac{1}{2}$ revolutions to the ſecond wheel of 60, which, therefore, makes juſt one revolution in Jupiter's period more than it would have done without the motion of the arm; the conſequence is, that the time of its revolution is leſs than $5\frac{1}{2}$ days, by a quantity that will amount, by accumulation, to $5\frac{1}{2}$ days in Jupiter's period. This quantity may be thus aſcertained; the period produced by Jupiter's wheels is 4330.72916 days; hence, as $4330.^{d}72916 : 4325.^{d}22916 :: 5.^{d}5 : 5.^{d}493014$; that is, as the whole period is to the period diminiſhed by 5.5 days, ſo is the whole time of the wheels' calculated revolution, to its diminiſhed period of a revolution: and as a proof of the correctneſs of this ſtatement,

ment, if we multiply the whole period of Jupiter by .006986, the difference between the two laſt terms, or the acceleration in each revolution of the wheel, the product will be 5.5 days, or an acceleration of one entire revolution in the ſaid period. Inſtead, therefore, of 5.5 days, we muſt take 5.493014 as the time of revolution of the remote wheel of 60, the arbor of which is made the common arbor of four other wheels, which drive each another wheel, ſoldered to as many tubes reſpectively, to carry the arms of the four ſatellites, as ſeen in the drawings. The wheels, with their reſpective periods correſponding, are contained in the ſubjoined table, where it is to be underſtood that the denominators of each fraction are the drivers made faſt to the arbor of 5.493014 days, and the numerators are the wheels faſt to the tubes reſpectively.

TABLE of Jupiter's Satellites.

The common arbor is held in a vertical poſition by two cocks, one above the end of the tube, and one below, which alſo holds the ſtem of Jupiter, round which the tubes revolve, and likewiſe the croſs piece ſeen in *Plate* VII. which ſupports a paper ſcreen for receiving the ſhadows of the ſatellites when a lamp is uſed; but when a lamp is not uſed, a conical piece of braſs fits on the ſtem behind Jupiter, to repreſent the ſhadow of his body, and to explain the immerſions or emerſions of the ſecondaries as they revolve. The diſtances of the ſatellites are taken in diameters of the ſmall ball that repreſents Jupiter. For a deſcription of other inſtruments, that have been conſtructed to anſwer this purpoſe ſeparately, we beg to refer to our article SATELLITE *Inſtrument*.

We have now arrived at the faces on the cover of the box, and the wheels that guide the indications, which will conclude our deſcription of this machine. On the vertical diurnal arbor that carries one of the bevel wheels at firſt deſcribed, is inſerted an adjuſtable hand that indicates mean ſolar time, on a rim of 24 hours fixed to the cover of the box: this rim is $3\frac{1}{4}$ inches in diameter, and $\frac{3}{8}$ broad; within this rim and in the ſame plane revolves a circular dial of 24 hours in a retrograde direction, juſt once in a ſolar year; and the ſame hand that indicates mean ſolar time on the fixed rim, indicates alſo ſidereal time on the revolving dial with equal accuracy; for as the revolving dial meets the hand the ſpace of $\frac{1}{365.242}$ of a circle ſooner in each ſucceſſive revolution, one day more in a year is indicated on this revolving dial than on the fixed plate, in the way that is done in Margett's chronometer, but with much more accuracy, as the train here between a day and a year is perfect. In order to produce this retrograde motion of the little dial of 24 ſidereal hours, one pinion only was neceſſary, which is fixed at the bottom of a tube that revolves round the diurnal arbor as a ſtud, and carries the dial on its upper extremity. It will be recollected that a pinion of 14, fixed to the annual arbor, drives a large wheel of 166 for the motion of Jupiter: now a ſimilar pinion of 14, placed over the bevel wheels, round the diurnal arbor, which is at the ſame diſtance as the annual arbor from the edge of 166, will act with it in this ſituation alſo, and will revolve in the ſame time that the firſt 14 does, which has been ſhewn to be a ſolar year. The intermediate wheel of 166 only tranſmits the motion unaltered, except as to its direction, which otherwiſe would not have been retrograde: thus from means the moſt ſimple, reſults of the utmoſt importance are derived, both as to utility and accuracy; and, what is not to be overlooked, the indication falls immediately under the eye of the lecturer, who muſt neceſſarily ſtand at the handle of the machine, while he is giving his lecture. The weekly vertical arbor, ſeen detached in *fig.* 2, ſtands at the ſame diſtance from the ſun, or centre of the box, as the other two arbors, and, as has been ſaid, forms with them an equilateral triangle. Another rim, ſimilar to the one juſt deſcribed, is alſo ſcrewed round the top of this arbor to the cover of the box, and contains the ſeven days of the week, which are pointed to by a hand placed in an adjuſtable manner on the projecting arbor, as ſhewn in *Plate* VII. This arbor alſo ſerves inſtead of a ſtud for two concentric tubes, one revolving in the ſolar year, and the other in the period of Jupiter: the former, or inner tube, is every way ſimilar to the one we have juſt explained, namely, a pinion of 14 takes the annual motion through the medium of Jupiter's 166, and carries this tube, to the upper end of which is adjuſted a ſecond hand, that indicates the time of Jupiter's meridian paſſage on any given day, upon an horary circular plate placed on the outer tube, which revolves in the period of Jupiter, and which is juſt large enough to fill the circular ſpace on the cover that was left within the fixed rim for the ſeven days: this motion is produced by means equally ſimple; the firſt wheel of the train that connects Saturn with Jupiter is 53, revolving faſt to the 166, and therefore in Jupiter's period, this wheel happens to occupy very nearly half the diſtance between the centre of the box and the weekly arbor, and therefore admits another wheel of 53 to act with it from this arbor, and this 53 revolving in the ſame direction as the 14 under it, and, in the period of Jupiter carries on its tube an horary dial, over which the annual hand paſſes in the ſynodic revolution of the earth, as compared with Jupiter. This little dial, if divided into 360°, would have ſhewn the diſtance of Jupiter to the ſun at any time, as ſeen from the earth, but it was thought to be more convenient to ſhew this diſtance in time, which therefore repreſents Jupiter's meridian paſſages when the index is put to XXIV on the day of Jupiter's conjunction with the ſun. In the ſame manner the time of culminating of any other planet might be indicated. Indeed, if an horary circle could conveniently be attached to the earth's arm, round the centre of its motion, under the large graduated circle of days, &c. the planetary arms would be ſo many indexes, though at ſome diſtance above and below it, to point out thereon the reſpective times of culmination of all the primary planets, agreeably to their mean motions. Jupiter's time of ſouthing is, however, a matter of daily importance, as it is a guide to his viſibility or inviſibility at any given hour, when the eclipſes of his ſatellites occur, and alſo ſhews whether the immerſions or emerſions of theſe ſecondaries take place; that is, whether Jupiter is before or behind the ſun, or, in other words, more or leſs than 12 hours from the ſun, as ſeen from the earth. Laſtly, the third rim, fixed to the cover of the box, round the annual arbor, has a circle of the ſun's declination engraven on it, and another circular face made faſt within it, juſt large enough to fill the vacant ſpace, on which face the reduction of the ecliptic to the equator is inſerted: theſe two faces require no additional wheelwork, but are pointed to by one hand adjuſted to the top of the annual arbor, over the

ſtack

ſtack of annual wheels. The reduction of the ecliptic to the equator, like the equation of the ſun's (or earth's) centre, marked within the large ecliptic circle, is given in degrees; and as theſe two cauſes of apparent inequality of the ſun's motion are given ſeparately, their ſum or difference (as the ſigns are the ſame or different) conſtitute the whole equation of time in degrees, which muſt be converted into time, at the rate of four minutes to a degree. Theſe contrivances afford the beſt poſſible means of explaining how the equation table is conſtructed of two different ſets of calculations, founded on diſtinct elements, and then combined into one quantity that comes to zero four times in the year, and that varies every day in a way that is not otherwiſe explicable, but that is thus rendered manifeſt to an ordinary arithmetician.

The pinions on the earth's arm may be any two of equal numbers, both above and below; likewiſe on Jupiter's arm, and at the earth's axis: and when the diameters are taken, it is underſtood to be acroſs from the pitch line to the pitch line, without the ends of the teeth, which will be inverſely in length, as the number of teeth *per* inch.

Orrery by Antide Janvier.—A French work has juſt come to our hands, entitled "Des Révolutions des Corps Céleſtes par le Méchaniſm des Rouages," 1812, Paris, by an eminent mechanic, whoſe contrivances have been honoured by an examination and report upon them, made by the claſs of phyſical and mathematical ſciences at the Imperial Inſtitute of France. The author of this work, which is a thin quarto with eight plates, begins his deſcription of his new planetary machine, which correſponds to our definition of an orrery, by ſaying that "while the arbiter of Europe, at ſix hundred leagues diſtance from his capital, is directing, under another ſky, the vaſt conceptions of his genius, and of his policy, in the obſcurity of our retreat, without a miſſion and without a title, we preſume to form an enterprize almoſt beyond the reach of our powers, at a time when our intellectual faculties have arrived at their full extent; but the favourable regard of the great Napoleon, the coup-d'œil of Maria Louiſa, the deſire of becoming uſeful to the inſtruction of an auguſt prince called to ſucceed to ſo much glory, and to bear ſo many diadems; what more can be wanting to ſupport our courage, to enliven our hope, and to furniſh us with new activity for the culture of an art, in which we have already obtained conſiderable ſucceſs!"—Such is the exordium to the deſcription of this machine, from the peruſal of which we had hoped to gain much uſeful information for the ſervice of our readers, as well as amuſement for ourſelves; but, to our diſappointment, the author has not favoured the world with an account of the numbers that conſtitute the teeth of his wheelwork, and gives as a reaſon for ſuch omiſſion, the exiſtence in Paris, which we do not doubt, of a faithleſs ſet of people, who have the aſſurance to avail themſelves of other men's labours, and to perſuade the world that they are their own. However, as there is conſiderable ingenuity manifeſted in the arrangement of the different parts of this machine, as contained in his plate IV. and as we truſt that we have rendered the methods of calculating ſuitable numbers for repreſenting any given period ſufficiently eaſy under our article NUMBERS *Planetary*; we ſhall give the ſubſtance of the account, as it is before us, and leave the reader to exerciſe his ſkill in determining for himſelf ſuch practical numbers as this particular conſtruction demands, which taſk will afford a variety of further examples to our theory. In *Plate* VI. of our ſeries, entitled *Planetary Machines*, we have given a reduced copy of the ſection of all the wheelwork of this machine, which bears conſiderable reſemblance to the following plate, which is the ſection of a new orrery conſtructed in England, immediately before the account, at preſent under our notice, arrived, andwhich we have deſcribed as being the moſt modern and comprehenſive. A A B B, in *fig.* 1. repreſents the ſection of a braſs frame kept together by the pillars *a*, *a*, and ſupported by a table $5\frac{1}{2}$ French feet in diameter, not ſeen in the plate. In this frame are contained the wheels for giving motion to the Earth, Mars, Jupiter, Jupiter's moons, and Saturn's moons; upon the upper plate of this frame is mounted a ſmaller frame, Y Y, ſupported by the ſhort pillars *z*, *z*, containing the wheels for giving motion to Saturn and Georgian, (or Herſchel,) and above this ſmall frame is another wheel for giving motion to the moons of Georgian. The interior planets Venus and Mercury have their wheelwork on the earth's arm, under the ſun, and the wheels for the ſatellites are at the extreme ends of the reſpective arms, while ſuch portions of the mechaniſm as could not be ſeen in *fig.* 1. are ſhewn in a detached ſtate in *figs.* 2 and 3. We ſhall retain the letters of reference of the author himſelf, and, in a great meaſure, his order of deſcription, but ſhall endeavour to avoid ſome of his repetitions. A long fixed axis of ſteel riſes out of the centre of the lower plate of the large frame, to which it is ſcrewed, by means of a circular ſhoulder-piece, faſt to the ſaid axis, into which axis the ſun S has its ſlender ſtem ſcrewed; the double wheel C D, with the part C contrate, turns in 48 hours, communicating motion to the earth's axis, and to our moon, by wheelwork placed at the upper end of a long tube, faſt to the double wheel, and revolving round the fixed ſteel axis; but this motion is taken from the wheel *x*, of half the ſize of the contrate wheel C, fixed on the horizontal arbor of the diurnal handle M. This arbor has two drivers fixed on it beſides *x*, namely, the contrate wheel *y*, driving the pinion *d*, and the pinion *b*, driving the contrate wheel E on a vertical arbor; to this arbor a ſecond pinion, *c*, is fixed, which drives the wheel F on another vertical arbor, and with it a ratchet wheel above, and the pinion *d*, before-mentioned, below it, and this pinion *d* again drives the wheel G in a year, which is therefore called the annual wheel. The pivot of the horizontal diurnal arbor is ſupported by the cock marked 13, and the arrangement of wheels and pinions which we have deſcribed is ſuch, that whether the handle of the diurnal arbor be turned round to the right or left, the annual wheel, G, will always proceed in the ſame direction, as may be thus explained: what may be called the ſlow motion, where $365\frac{1}{4}$ turns are made in a year, is tranſmitted through the ſucceſſive pinions *b*, *c*, and *d*, to the wheels E, F, and G, in the regular way; but when a retrograde motion is given to the handle, the pinion *d* is driven by the contrate wheel *y*, with a velocity one hundred times increaſed, and yet in the ſame direction as before; the wheel *y* has alſo a ratchet wheel behind it, like as the wheel F has, which ratchets allow their contiguous wheels to move looſely round their arbors one way round, but the clicks faſt to the wheels catch the teeth of the ratchets when going the other way, and attach them to their arbors reſpectively; but whenever the click of ratchet F impels this ratchet's teeth, the click of ratchet *y* ſlides without entering its teeth, and *vice verſâ*, the two ratchets having their teeth ſo ſloped in oppoſite directions, that they never oppoſe each other's action, but, on the contrary, when one ceaſes to act, at the inſtant the handle retrogrades, the other begins, and thus the pinion *d* continues its motion in the ſame direction at all times, if the handle move at all; but when the contrate wheel acts as its driver, its velocity becomes increaſed one hundred times, by being derived immediately from the handle through the wheel *y*, while the wheels E and F, with the pinion *c*, are moving in a detached ſtate, and in a reverſed direction, thereby producing no effect on the pinion *d*, which is alſo the caſe with wheel *y*, when the handle goes by a direct motion. This contrivance for giving both ſlow and quick motion alternately, is ſimple but ingenious, and the author ſays he introduced a contrivance for making all the planetary bodies move backwards, when required, as well as forwards, which cannot be done with the ratchet acting in the uſual way; but he has not thought proper to explain his method; though he ſays that it is by the uſe of the quick motion that the backward motions are effected by a third contrivance. This contrivance, however, becomes obvious on a little reflection, which may be thus: the exterior end of the diurnal arbor may be lowered by a ſliding motion of its bearing-piece, till the teeth of pinion *b* are detached from wheel E, while yet the teeth of the contrate wheel *y* will continue in action in pinion *d*, by reaſon

of its being nearer the interior end of the horizontal diurnal arbor, which is therefore not ſo much lowered as the exterior end, while the interior pivot remains in the hole of its cock: it will be neceſſary, notwithſtanding, to pin the ratchet to wheel *y*, for the time that this wheel is made to act in both directions, which may be readily done when a hole is drilled through both the ratchet and wheel *y* at the ſame diſtance from their centres of motion, and by the ſame drill. The tube of the annual wheel G turns immediately upon that of the double wheel of 48 hours, but reſts on the bridge 13, which ſupports the ſuperincumbent weight of the mechaniſm borne by this annual tube. Under the annual wheel G is made faſt to it the ſmall wheel *e*, that drives the wheel *f*, on a ſeparate vertical arbor, reſting on the bottom of the large frame, and ſupported at top by the braſs plate Y Y, in the upper or ſmall frame, which plate is ſaid to be circular. On this vertical arbor of *f*, are made faſt three other drivers, one wheel and two pinions, denoted by the letters *g*, *h*, and *i*; wheel *g* drives the tubed wheel H in the period of Mars; *h* drives the wheel I with its tube in the period of Jupiter; and *i* drives the wheel K in the ſmall or upper frame, in the period of Saturn. The bridge 14, above the annual wheel G, has a tube fixed to it, as ſeen in *fig.* 2. along with bridge 13, without a tube. The uſe of this tube will be ſeen preſently. To the wheel I of Jupiter is made faſt the ſmaller wheel *k*, which drives wheel A, placed on another vertical arbor, ſeen in *fig* 3. detached, which arbor is ſupported behind the other works, in the manner that we have deſcribed the arbor of wheel *f* to be; then wheel B, on the upper part of this vertical arbor, drives wheel L in the ſmall frame above K, in the period of Georgian; hence the revolutions of Mars, Jupiter, and Saturn, are trains from the motion of a year, but the revolution of Georgian is by a train from the motion of Jupiter. Above the upper frame is placed a cock C, ſeen in *fig.* 3, which ſupports the fifth and laſt vertical arbor, with the wheels 10, 11, and 12 faſt to it, at different heights, proportioned to the heights of their fellow wheels; wheel 10 takes its motion from wheel D of 48 hours, and wheel 11 drives N, which has a quick motion of 48 hours alſo, if we may judge from the comparative diameters of theſe four wheels, D and N appearing to be each double to 10 and 11; but the pinion 12, at the top of the fifth arbor, drives wheels *o* more ſlowly, for the firſt mover of Georgian's ſatellites. The bridge 15 has alſo a tube faſt to it, which will have its uſe deſcribed in its place. The reſt of the mechaniſm which follows ſtands above the frame, and is in ſight, which we will now proceed to deſcribe, as we aſcend from the frame. The large contrate wheel *o*, with its teeth pointing upwards, is faſt to the top of the tube of wheel O above the frame, that revolves round the tube of wheel L in the ſmall frame; this wheel *o* gives motion to Georgian's ſatellites, by means of the long pinion ſeen over it, which is carried round by Georgian's arm in his period, with their teeth in connection, on which account this long pinion has a compound motion, one part of which is derived from the revolutions of wheel *o* coming more immediately from the handle, and the other ariſes from the motion of the arm that carries the pinion round the large wheel in Georgian's period; this ſecond portion, being in the ſame direction as the principal motion, produces an acceleration in the motion of the pinion, of as many revolutions as its teeth are contained in thoſe of the wheel, during the whole period of Georgian. The arm is not, as uſual, placed on the top of Georgian's tube, but turns round an excentric circular piece of braſs W, attached to the top of a tube, borne by the plate, Y Y, of the ſmall frame, and receives its motion from a pin 3, at the remote end of a bar 3 7, which bar is inſerted on the tube of Georgian's wheel L, and revolves in his period; hence the arm itſelf revolves round the excentric piece, W, as its centre of motion, and therefore the planet carried by it has its diſtance and velocity conſtantly changing in every part of its orbit, as have alſo the ſecondaries, in a certain degree. But it is not mentioned what proportion the excentric point, or centre of piece W, meaſured from the centre of the concentric tubes, bears to the whole arm, or radius vector: if it is in the ſame ratio as the excentricity of the orbit itſelf is to the planet's mean diſtance, then the variation of diſtances will be properly enough repreſented in the excentric orbit, but the equations of the centre will be only one-half its due quantity; on the contrary, if the excentric point be placed at double the diſtance of the proportional excentricity of the orbit, then the equation will be right, but the variation of diſtances will be too much by one-half; which obſervation is equally true, as it reſpects the other excentric arms hereafter to be deſcribed. The arm of Georgian has a long opening in the direction of its length, to admit the pin 3 to paſs through it, which therefore acts like the crutch of a clock, except that here the motion imparted is always in one direction. The horizontal arbor of the long pinion has another pinion at its remote end, that is not required to be long, becauſe its action is not with a wheel that is perpetually altering the effective length of its radii, as is the caſe with the large wheel o. The ſix moons of Georgian receive their motion from this ſhort pinion thus; the contrate wheel, *c*, is made, by the calculation, to revolve in the period of the firſt ſatellite, or in $5^d\ 21^h\ 25^m$, and carries wheel *d* round with it in the ſame period; then wheel *e* takes this motion, whether modified or not does not appear, and its arbor takes four pinions, one above another, which drive each its fellow, on a ſmall tube, in the reſpective periods of the 2d, 3d, 4th, and 5th ſatellites; but the period of the 6th ſatellite, being comparatively long, is taken from the period of the 5th, by the wheel *a* driving *b* on a ſeparate arbor in $38^d\ 1^h\ 49^m$; while a ſecond pinion, placed over it, drives the wheel R, of the 6th ſatellite, in its period of $107^d\ 16^h\ 40^m$. From a conſideration of this combination of wheels and pinions, the reader will ſee that Georgian's moons, like the long pinion, have their mean motions accelerated in one part of this planet's orbit, and retarded in the other, by reaſon of the long arm having its centre of motion out of the centre of the large wheel's motion; the latter of which may be ſaid to give the mean motions, and the former the equations, or variations that derange thoſe mean motions, and that depend on the place of Georgian's anomaly at any time. In like manner, Saturn and Jupiter have their ſyſtems of moons actuated by the double contrate wheel *n n*, carried by the tube of wheel N before deſcribed: the teeth that point downwards drive Saturn's moons, and thoſe that point upwards Jupiter's. The excentric piece, round which Saturn's arm revolves, is marked Z on the fixed tube of the plate A A of the frame; and the bar 5 6, that impels this arm by the pin 6, is faſt to the tube of wheel K in the ſmall frame: the long pinion, carried round by the arm of this planet, is in connection under the wheel *n n*, which impels it, but experiences the ſame ſort of acceleration that we have deſcribed in the caſe of Georgian's long pinion: the ſhort pinion at the remote end of the arm acts alſo under the teeth of its contrate wheel *a*, that, we are told, revolves in $0^d\ 22^h\ 40^m\ 4.^s6$, or period of the firſt of his ſeven ſatellites. From this period wheel *b*, on a ſide arbor, takes its motion, and carries four other pinions above it, which drive their correſponding tubed wheels 2, 3, 4, and 5, in the periods of the 2d, 3d, 4th, and 5th ſatellites; from the

period

period of the 5th, *viz.* $4^d\ 12^h\ 27^m\ 55^s$, the wheel *c* gives motion to another ſide arbor, by means of wheel *d*; and this laſt arbor carries again two driving pinions, that impel the two laſt wheels 6 and 7, the latter of which, near Q, is ſaid to revolve in $79^d\ 22^h\ 3^m\ 12^s$. Again, Jupiter's arm, *t t*, revolves round the excentric piece *q*, placed on the tube of bridge 15, and is counterpoiſed by the weight *t* 3; this long pinion, *a*, acts, like Georgian's, above the large double contrate wheel *n n*, and experiences a ſimilar acceleration to that of Saturn in kind, but not in quantity; for the excentric pieces are of different dimenſions, and each is placed in the direction of its own line of the apſides: the bar 3 4, on the tube of wheel I, drives this arm by the pin 4, entering the oblong perforation in the arm *t t*, and the ſhort pinion, *b*, drives the contrate wheel, *c*, at the remote end of the arm, in $1^d\ 18^h\ 28^m\ 36^s$, the period of the firſt ſatellite of this planet; the wheel attached to this contrate wheel, *c*, drives *d*, on a ſide arbor, and with it three more pinions on this common arbor, each of which impels its fellow 2, 3, and 4 reſpectively in the periods of the 2d, 3d, and 4th ſatellites. The little arms of all the ſatellities are connected with as many tubes, taking their motions from the laſt moving wheels, as ſeen in the drawing, without further deſcription; but it will have been remarked, that all theſe ſecondaries in this machine are made to move in the ſame plane with that of the ecliptic, which in nature is the caſe with Jupiter's only; conſequently the motions of both Georgian's and Saturn's moons, however accurately their periods may be produced by the wheelwork, are in improper directions relatively to the orbits of their primaries, as well as to all the other parts of the ſolar ſyſtem Next above Jupiter comes the arm of Mars, revolving round the excentric piece *p*, placed on the tube of bridge 14, and impelled by the pin 2 of the bar 1 2, attached to the tube of wheel H: this planet, conſequently, has an excentric motion in his orbit; but having no moons, requires only a ſimple arm. Over Mars is placed the Earth's annual arm with its appendages, which are neceſſarily on a ſmall ſcale, and which the author has put in an enlarged ſection on a ſeparate plate, containing the mechaniſm for the earth's paralleliſm and diurnal rotation, the periodic motion of the moon, and the retrogradation of the nodes of her orbit, together with the revolutions of Venus and Mercury round the ſun; all which we will now deſcribe in ſucceſſion. The wheel *r* is fixed faſt to the tube of bridge 14, and *s s*, the earth's arm, or annual frame, revolves with the tube of the annual wheel G, before deſcribed: the wheels under this frame are deſtined to preſerve the paralleliſm of the earth's axis, in order to do which exactly, the firſt and third wheels muſt be of like numbers, with any number for the intermediate one to change the direction of motion; but the author propoſes a train that may make the pole of the ecliptic have a revolution in 25,670 years, or to fall back one degree in 72 years, for effecting the preceſſion of the equinoctial points: the train that he propoſes to uſe for this purpoſe, to be ſubſtituted for the ordinary wheels of paralleliſm, are $\frac{151}{133} \times \frac{170}{193} = \frac{25670}{25669}$, in which fraction there is a difference between the numerator and denominator of unity; or $\frac{1}{25670}$ part of the whole would be the annual quantity of deviation from ſtrict paralleliſm; but it is eaſy to ſee, that the adoption of theſe large numbers would require the earth's arm to be much longer than its proper proportion in the machine requires to contain them; or otherwiſe the excentric pieces would require to be greatly, and therefore inconveniently enlarged, by adding to the length of the planetary arms, and the long pinions would by ſuch alteration become too much elongated for due action in both ſemicircles of their reſpective wheels. On the top of the axis of the third wheel of paralleliſm is ſupported the earth by an exterior ring, into which his axis is pivoted above and below, and by means of which any quantity of inclination may be given to this axis, with reſpect to a perpendicular line. The ſecond, or intermediate wheel of paralleliſm, has however the ſame number of teeth as the other two, with which it is connected, and has a vertical arbor ſupported by the ſame cock under the earth's arm, that ſupports the arbor of the third wheel and the earth above it; we ſhall preſently ſee the uſe of this, which we will call the annual arbor, as it revolves juſt once in each year: juſt above the earth's arm revolve alſo three other wheels, *u*, *v*, and *w*; the wheel *u* is on the tube of C D of 48 hours, *v* revolves in the ſame time, but *w*, having only one-half the number of teeth, makes a revolution in 24 hours, or rather would do ſo if the earth's arm had no annual motion; but by reaſon of the annual motion, the wheel *w* receives two additional revolutions in the year, and theſe two additional revolutions are balanced by a drawback of two days, occaſioned partly by the retrograde motion of the wheel of paralleliſm, which carries the pinion of the earth's axis once round the central pinion on the tube of 24 hours motion, thereby making it revolve, and partly by the earth's circuit round the ſun, whilſt the axis preſerves its paralleliſm, by which circuit the ſun appears to move retrograde round the earth once in a year. This balance of the two oppoſite compound motions has been minutely explained in our deſcription of the preceding inſtruments, to which the reader is referred. The little earth has beſides two interior circles ſurrounding it, one for a meridian circle, and the other for an horizon, which is adjuſtable for any latitude, by ſliding up and down within the other, while the pivots of an equatorial fixed axis allow the horizon circle to turn on them for effecting the different degrees of inclination. The moon's monthly motion is taken from the ſecond wheel of 48 hours by a train of two pinions, and as many wheels, ſeen in the figure, ſupported by the two cocks above the annual frame. We have already ſaid that the ſecond, or middle wheel of paralleliſm, under the annual frame, has a vertical arbor, which we propoſed to call the annual arbor: on the upper end of this is a wheel which drives the nodes wheel round in its period of $6798^d\ 4^h$, and the tube of this wheel carries the inclined plate on which the moon's ſtem reſts during her monthly motion in the uſual way. Again, the upper wheel on the annual arbor, which is repreſented in a line with wheel *x*, but which is actually on one ſide of it, and in contact with it in the machine, gives motion to this wheel *x*, on an arbor that has beſides both a pinion and a wheel made faſt to it: theſe two, revolving together probably in the ſpace of a year, drive each a correſponding wheel and pinion, namely, the pinion for Venus drives wheel *y*, and the wheel for Mercury the pinion *z*, each with its reſpective tube and attached arm, in their due periods. In this arrangement, the planets Venus and Mercury, as alſo the Earth and Moon, move in their orbits with equable motion; but in the enlarged ſection above alluded to, the author recommends the introduction of an excentric piece without a fixed tube (which, indeed, cannot be here introduced), but a pair of wheels are propoſed to be added to preſerve the annual paralleliſm of this excentric piece, thereby rendering the mechaniſm more complex than uſeful, as it relates to Venus; for this planet has but little excentricity in its orbit, and conſequently a very ſmall equation of its centre. The ſuggeſtion of this mechaniſm, which does not appear to have been adopted, is intended apparently to ſhew the ingenuity of the contriver rather than the utility of its

adoption in practice. The little wheels for the parallelism of the moon's phase are also proposed in the larger section, but not introduced on the moon's arm in the machine, by reason of the scale on which the excentric pieces demand that the machine should be constructed, to have easy motion. The four newly discovered planets are entirely omitted in this construction; for which omission the author apologises, by stating how they might have been added from Jupiter's arm, as Venus and Mercury have their motions taken from the Earth's annual frame; but the great excentricity of some of these four orbits, no doubt, presented difficulties more easily explained away in theory than overcome in practice, where, at the least, two excentric pieces must have been introduced without any tubes to support them on, except such as must have been made stationary by the opposition of two equal motions produced in contrary directions. Hence the author's original idea of giving motion to *all the primary planets*, and to their secondaries, which he says he at first contemplated, was not put in execution. In our opinion, the orrery would have been more complete if all the primary planets had been represented in motion, with such of the secondaries only as are useful in astronomy, geography, or navigation, and as are to be seen with telescopes of moderate magnifying powers, which was the plan proposed by the inventor of the machines which were immediately before described.

After having particularized the different orreries that appear to us worthy of public notice, we conceive that it will be rendering the instrument-maker an acceptable service, if we subjoin here such tables of the sun and moon as are necessary for graduating the different plates of indication for exact degrees and parts of a degree, which could not be done from the ordinary tables, where the arguments, or angular distances, are given in whole degrees, and the corresponding equations, &c. in degrees, minutes, and seconds; whereas the former are required to be in degrees and minutes, and the latter in whole degrees, halves, and quarters, to represent the dividing strokes. The conversion of the tables into other terms of the same relative values, has been a work of some labour, but was necessary for our purpose; and the tables thus arranged will afford the ready means of laying down the dividing strokes of each graduated circle, by the help of any of the usual modes of measuring angular distances along the circumference of a circle. For instance, suppose the moon's mean heliocentric latitude were to be inserted on a plate; with the extent 2° 47′.2 from Tab. V. in the dividers set off both ways from each node, and the stroke 0° 15′ will be given in four places: again, with the extent 5° 34′.9 set off for the strokes 0° 30′, and in like manner for any other dividing stroke that is required in any of the divided circles.

In *Plate* IX. of *Planetary Machines*, we have given the eight circles, properly graduated from theſe eight tables, a compariſon of which, with their reſpective tabulated numbers, will render the method of putting in the dividing ſtrokes perfectly intelligible. The tables proper for the equations, latitudes, &c. of the other planets will be given under our article PLANETARIUM, where it is hoped we ſhall be able to include thoſe of the four newly diſcovered planets, ſome of which we have already calculated.

ORRERY, *Rectification of.* The orrery has heretofore been conſidered as a machine, ſerviceable only for general illuſtration, and in its former unimproved ſtate its powers were certainly very limited, both as to accuracy and extent; but in the hands of a ſkilful inſtructor, the improved orreries, which, for the firſt time, we have now preſented to the ſcientific world, are capable of explaining, with conſiderable minuteneſs, the principal phenomena of the Copernican

ſyſtem, and thoſe in the moſt natural way. It would lead us beyond our original intention to arrange and exemplify a ſyſtematic ſeries of problems, that may be ſolved by the moſt improved orrery, which we hope ſoon to ſee publiſhed in a ſeparate pamphlet; but we conceive our article will not be conſidered as complete without the addition of ſome general precepts for its rectification, that may enable its poſſeſſor to avail himſelf of its extenſive powers in ſuch way as may be moſt ſubſervient to his purpoſe. We muſt take for granted that the proprietor of an orrery has provided himſelf with a ſcrew-driver, and that he is able to take in pieces, and to put together, ſuch parts of the machine at leaſt as are neceſſary to be detached, either for package and carriage, or for adjuſtment; whether theſe parts are kept together by clamping pieces, or by cloſe fitting by means of friction. Our precepts ſhall not be confined to any particular conſtruction, but ſhall include what is moſt neceſſary to be done in any of the machines for giving inſtruction.

If we ſuppoſe the machine to be of the moſt comprehenſive kind, the rectification of it will contain all that is requiſite for rectifying any of the more limited ſort, and therefore we will ſuppoſe that all the primary planets, and the Earth's and Jupiter's ſecondaries, are to be put to their reſpective ſituations for a given time. It has been uſual to put the primary planets in the common orreries and planetaria, where the motions are *mean*, to their apparent or *equated* places, as ſhewn in the Nautical Almanac, or in White's Ephemeris taken from it, as though the mean and equated places were the ſame; whereas they never coincide, except in the perihelion and aphelion points of their reſpective orbits: when, therefore, an orrery is to be rectified for a given time, the firſt conſideration is, whether the motions are *mean* or *equated*; if they are the former, the places of the planetary bodies, ſo moving, muſt be aſcertained from the tables of mean motion reſpectively, which we have given, or may hereafter give, in their places, and then the reſpective equations of the centre, depending on their diſtances from their aphelion points, as exhibited in the proper tables, will give the true, apparent, or equated places, which epithets mean the ſame thing; but if the conſtruction of the orrery be ſuch, that the equated places are at all times repreſented by ſome ſort of equation mechaniſm, then the Nautical Almanac, or White's Ephemeris, will be a ready and proper guide for rectification; though when theſe are neither of them at hand for the given year, the tables that give both the mean motions and equations may be ſubſtituted. In general it will be found moſt convenient to adjuſt the planetary bodies to their places for the beginning of the year, if the motions repreſented are *mean*, becauſe they are given in the tables without calculation, and then turning the handle till the annual index arrives at the given day, will put all the bodies that have motion to their reſpective mean places for the day ſo indicated; but where the equated motions are produced, the rectification may be made from the almanac with equal convenience on any day of the year, that is there ſpecified as having the heliocentric places ready calculated. For the ſake of exemplification we will take the beginning of the year 1813, as the time for which an orrery, for either mean or equated motions, is required to be rectified, and the requiſite places will be found, as they appear in the ſubjoined table; *viz.*

Planets.	Mean Longitude.	Aphelion.	Mean Anomaly.	Equation of the Centre.	Heliocentric and equated Longitude.
	s o ′ ″	s o ′ ″	s o ′ ″	s o ′ ″	s o ′ ″
Mercury - -	3 8 48 36	8 14 33 2	6 24 15 34	+ 0 12 28 50	3 21 17 26
Venus - -	6 12 15 29	10 8 46 43	8 3 28 46	+ 0 0 42 30	6 12 57 59

Moon's node -					4 21 47 0

In this table the firſt column contains the names of the planets; the ſecond gives the mean longitudes from the tables of the epochs; the third ſhews the place of the aphelion or apogee reſpectively; the fourth gives the difference between the ſecond and third columns, when the latter is ſubtracted; the fifth contains the correſponding equation of the centre, taken from the table of mean anomalies, and the ſixth ſhews the ſum or difference of columns 2 and 5, which is the equated longitude as ſeen from the ſun. This laſt column would be the ſame as the column of heliocentric longitudes in the almanac, if the minor equations had been attended to, as contained in th tables; but the amount of theſe is ſo ſmall, that they may be neglected without ſenſible error in the adjuſtments of the planetary bodies, when the places are not taken from the almanac. In this manner a table may be eaſily conſtructed for the beginning of any particular year, but let it be remembered that the epoch for the planets begin the year on December 31, 1812, but the ſun (or earth) and moon on January 1, 1813, at noon, according to Lalande's tables: alſo that the place of the earth muſt be taken juſt ſix ſigns from that calculated for the ſun from the ſolar tables. Whenever an orrery for mean motions is rectified it muſt be from column 2, and the equation in column 5 ſhews, by reverſing the ſigns + and −, how much the place is before or behind the *apparent* or *true* place at the beginning of the year; as for any other time the longitude of the aphelion muſt be taken from the place of mean motion, for the mean anomaly, as the argument for the correſponding equation to be added or ſubtracted, accordingly as the quantity is more or leſs than ſix ſigns: but when an orrery

that

that produces equated motion is uſed, the laſt column contains the proper places for the planets to be rectified by; and, when once rectified, ſuch machine will require no further calculation for any ſubſequent equation, becauſe the planets move through equal areas in equal times, as in nature. We might have added another column for the heliocentric latitude of the planets, but as theſe are given (except for the four newly diſcovered planets) in the almanac, it would be adding to the labour of conſtructing ſuch table, without producing a correſponding advantage. In putting the planetary arms to the places laid down in the table, a ſilken thread carrying a ſmall plummet will be uſeful to hold up in ſuch way, that the eye may view it biſecting both the planetary ball and the ſun, leſt there ſhould be too great a parallax in the place of the planet, when placed without ſuch guide to its proper ſign and degree. It may be unneceſſary to add, that the exact place of the planet in the ecliptic circle ſhould be covered by the thread when it biſects both the planet and ſun.

When the mean motions are uſed, the equations of the centre may be allowed for by a joint in the perpendicular ſtem of the arm, and then the geocentric places may be obtained by ſtretching a ſilken thread from the earth's ſtem acroſs the ſmall ecliptic circle to any particular planet, at a given time; but in the orreries for equated motion no ſuch manual allowance will be neceſſary. We will now ſuppoſe the arms adjuſted to the heliocentric longitudes, mean or equated, as the caſe may be; and that the earth and moon want adjuſting: let the moon be firſt put to her longitude, after the ſmall ecliptic circle is made parallel to the outer or large one, by means of the ſilken thread extended over the ſimilar diviſions of both; then adjuſt the nodes plate, and apogeal index, together with the lunar plate for the moon's age, tides, phaſes, &c. according to the calculations in the table, or places given in the almanac; after theſe adjuſtments, which ſhould leave the centre of the moon at the ſame height as the centre of the earth, when the moon has no latitude, the circles of the globe muſt be put ſuitable to the latitude for which the problems are to be performed, as well as for the longitude; that is, the meridian circle muſt paſs over the given place, and the horizon circle muſt have it equidiſtant from every part of its circumference, or, in other terms muſt have the ſaid place in its pole; theſe circles, once fixed acroſs one another at right angles, muſt not be altered till ſome problem is to be ſolved for a new latitude or longitude, or both, as the caſe may be; but muſt be ſuffered to revolve with the earth, care being taken that the eaſtern and weſtern points of the horizon circle biſect the globe when the adjuſtment is finiſhed, and alſo that the points of the meridian circle, in contact with the horizon circle, be at the latitude and co-latutide of the place reſpectively.

Adjuſt now the lens for converging the ſolar ray to the height of the earth's and moon's centres, and give it the proper focal diſtance, and examine that the direction of the earth's axis be parallel to a line joining the ſolſtitial points: if theſe adjuſtments are all properly made, the luminous focal point will fall on the tropic of Cancer at midſummer, on the tropic of Capricorn at midwinter, and on the equator at the equinoxes. The proper inclination of the earth's axis will be proved by trying if the focal point will keep in the ecliptic circle of the globe from the vernal equinox to the ſame again, when the annual motion is given without the diurnal, while the parallelism is preſerved. When theſe adjuſtments are finiſhed, bring the meridian circle to the ſolar ray, and put the horary index to noon; and if both ſolar and ſidereal time are indicated by the ſame dial, the diſtance between the two hands muſt be put equal to the ſun's mean right aſcenſion at the time, and then the two hands will coincide when the ſun enters Aries, which therefore is the beſt time for examining the relative poſition of the ſaid hands. Laſtly, let the week hand, the hand for Jupiter's meridian paſſage, and ſuch other hands as there may be yet unadjuſted, be put to their proper places, and take notice that all the motions of the hands and planets begin with the motion of the handle, as nearly as may be, which may be managed by turning till the wheels are all in action before the hands are finally placed. When all the adjuſtments are finiſhed the orrery ſhould be ſo placed that the pole of the earth may point towards the correſponding pole in the heavens, and then the motions of the different bodies will be referred to their correſponding places in the heavens, on each ſide of the earth.

With reſpect to the ſatellites of Jupiter, the table of immerſions and emerſions in the Nautical Almanac, or Ephemeris, will be the moſt convenient guide for rectification, the application of which is obvious by mere inſpection. Thus, the neareſt immerſion of the firſt ſatellite to the beginning of the year 1813, is on the 31ſt of December 1812, at $9^h\ 38^m$, and the next ſubſequent one on January 2, 1813, at $4^h\ 6^m$ nearly; the ſecond has its immerſion into the ſhadow of Jupiter on December 31, 1812, at $5^h\ 26^m$, and again on January 3, at $18^h\ 44^m$ nearly; the third on January 1, at $16^h\ 46^m$, and its emerſion, or departure out of the ſhadow, at $20^h\ 17^m$ nearly; and laſtly, the fourth has its immerſion on January 11, at $16^h\ 9^m$, and its emerſion at $20^h\ 32^m$, neglecting the ſeconds, which cannot be eſtimated in the orrery.

If, however, theſe calculations are not at hand, or if the time required is paſt, or future, the epochs in the tables will give the times of a mean conjunction, which may be converted readily into an apparent conjunction by applying the equations A, B, C, &c. as given in De Lambre's tables; or the equation A, depending on Jupiter's anomaly, together with the equation for the action of Jupiter in the given year, will ſuffice for our preſent purpoſe, without the application of the minor equations, as may be ſeen in the following ſmall table.

	1 Sat.	2 Sat.	3 Sat.	4 Sat.
	D. H. M.	D. H. M.	D. H. M	D. H. M.
1813, Epoch	0 8 43	0 3 25	1 12 15	11 3 6
Equat. A	1 51	3 8	5 43	12 35
1813, 24	4	9	18	41
Conjunction	0 10 38	0 6 42	1 18 16	11 16 22

Theſe times of mean conjunction may be turned into apparent times by applying the equation of time as given in the Almanac, and a compariſon of the reſults with the immerſions and emerſions, as given above, will ſhew that the times of conjunction here given are earlier than the emerſions, but later than the immerſions, as they ſhould be, by reaſon of the continuance in the ſhadows reſpectively.

When the lamp is uſed for the ſun, the little paper ſcreen, at the extremity of Jupiter's arm, receives the ſhadows of the ſatellites, as well as of Jupiter himſelf, and the perpetual change taking place in the apparently vibratory motions to the right and left of Jupiter before and after they paſs before his body, or through his ſhadow, affords a pleaſing object of contemplation, while the exact time of each configuration is marked by the ſame hour index that points out the time of any other contemporary

phenomenon, that is taking place in any other place in the ſyſtem, when all the bodies are moving together with their reſpective velocities, mean or equated, as the conſtruction directs. The ring of Saturn muſt be ſet to have an inclination of about 30° with the planet's orbit, and the line of the nodes muſt yearly be put parallel to a diameter of the ecliptic circle taken from 5ˢ 20° 52′ to 11ˢ 20° 52′, in order that a ſpectator at the earth may ſee the ſhape of the opening between the ring and the body of the planet in any year; but when the paralleliſm of the ring is preſerved by the mechaniſm, frequent adjuſtments are unneceſſary. The planes of all the orbits of Saturn's ſeven ſatellites are nearly parallel to that of the ring, except that of the ſeventh, which is ſuppoſed to make an angle of about 16° with the common plane of the others. The orbits of the ſatellites of Georgian are ſuppoſed to be pretty nearly at right angles with the orbit of the planet, but are perhaps not ſufficiently aſcertained. We mention theſe particulars, becauſe in the common inſtruments the orbits of all the ſecondaries are repreſented as being parallel to the orbits of the primaries, which repreſentation gives a falſe idea of the ſyſtem.

We might laſtly proceed to illuſtrate the various phenomena ariſing out of the relative motions of the different heavenly bodies, by way of exemplifying the uſes of the orrery; but this agreeable exerciſe of our time would involve us in ſuch an endleſs variety of ever varying problems, that a whole volume might be filled in detailing the various combinations of motion, that conſtitute the ſubjects of aſtronomy, dialling, navigation, and geography; and that may be illuſtrated by a proper management of the orrery; particularly when the globe is large enough to admit of a quadrant of altitude to determine by meaſurement the altitudes and azimuths of the ſolar and lunar rays, or luminous points, on the ſurface of the globe, that indicate at all times, when the lamps are uſed, the vertical places of thoſe luminaries, or the places where they would be ſeen through the earth's ſurface, ſuppoſed to be tranſparent, when viewed from the centre of the earth; for as the earth's ſurface is globular, and parallel to the apparent circle of the heavens, any meaſurements of angles, or of angular diſtances, as they regard the circles ſurrounding the earth, will have the ſame reference to theſe luminous points, as actual meaſurements would have of the ſun's and moon's places ſeen in the heavens. Laſtly, when a ſphere, which has not hitherto been mentioned, but which Mr. Pearſon's larger orrery has got, is fixed round the earth, on the tube of paralleliſm, and has a number of ſtars attached to it, thoſe ſtars continue parallel at all times to the ſame ſtars in the heavens, and the ſolar and lunar rays travel from ſtar to ſtar, in their revolutions, and explain the occultations, and other relative appearances, together with the hour of their occurrence, and places to which they are viſible, in a manner that is truly gratifying.

ORRHAGOGA, formed of ορος, *ſerum*, and αγω, *I draw away*, a name given by the ancients to ſuch medicines as operated violently, as purges, and evacuated ſerous and watery humours.

ORRHOPHIGION, a word uſed by anatomical authors, ſometimes to expreſs the extremity of the ſpine, but more frequently the line or ſeam which runs from the penis along the middle of the ſcrotum to the anus.

ORRHOPISSA, a name given by the ancients to the thinner or more fluid parts of tar.

ORRIA, in *Geography*, a town of Spain, in Aragon; 9 miles N. of Teruel.

ORRICE, a name given by the vulgar to the iris root.

ORRINGTON, in *Geography*, a town of America, in Hancock county, Maine, at the head of the tide on the E. ſide of Penobſcot river, oppoſite to the towns of Bangor and Hamden; 32 miles northerly from Caſtine, and containing 785 inhabitants.

ORRIO, El, a town of Spain, in Biſcay; 15 miles S.E. of Bilbao.

ORRON Water, a river of Scotland, which runs into the Frith of Cromarty, at Dingwall.

ORRSVILLE, a town of America, in Grainger county, and ſtate of Tenneſſee; 501 miles from Waſhington.

ORRUS, in *Botany*, a name by which many of the ancients called the cultivated pine-tree, from its being remarkably full of juice.

The firſt perſon who has given us the name is Theophraſtus; but he is followed in it not only by the other Greeks, but alſo by the Latins, who have called the ſame tree for the ſame reaſon *ſapinus*, a contraction or abbreviation of the word *ſapapinus*, the juicy pine. Pliny tells us, that this laſt was the name of the manured pitch-tree; but in this he errs; for Vitruvius, and others, tell us, that the pine nuts, *nuces pineæ*, which were eaten and uſed in medicine, were the fruit of the *ſapapinus*, or *ſapinus*; and it is evident that theſe muſt be the produce of a pine-tree, not of a pitch-tree, or any thing of the fir kind.

ORSARA, in *Geography*, a town of Naples, in Capitanata; 4 miles S. of Troja.

ORSATO, Sertorio, in *Biography*, an eminent antiquarian, was born at Padua in the year 1617. At a very early age he exhibited a great turn for literary and ſcientific purſuits, and occupied himſelf very much in the ſtudy of ancient monuments and inſcriptions. In the latter part of his life he was appointed profeſſor of natural philoſophy in the univerſity of Padua. He died in 1678, leaving behind him many works of great erudition, as well in the Latin as in the Italian language. Of theſe the principal are, "Monumenta Patavina;" "Commentarius de notis Romanorum," a uſeful treatiſe reſpecting the marks and abbreviations uſed by the Romans in their writings and inſcriptions; it was publiſhed in the eleventh volume of the collection of Grævius, and afterwards at Paris in 1723; "Prænomina, Cognomina, et Agnomina antiquorum Romanorum;" "Deorum, Dearumque Nomina et Attributa;" "A Hiſtory of Padua," in the Italian language; alſo, "Poems and Orations," in Italian and Latin. He was a member of various learned ſocieties.

ORSCHA, in *Geography*, a town of Ruſſia, in the government of Mogilev, on the Dnieper; 40 miles N. of Mogilev. N. lat. 54° 30′. E. long. 30° 14′.

ORSERA, a ſea-port town of Iſtria, ſeated on a hill, with a fine harbour, which affords ſhelter in tempeſtuous weather. It is populous, and the reſidence of the biſhop of Parenzo; 4 miles N. of Rovigno.

ORSI, Lelio, in *Biography*, called *Lelio da Novellara*, from the chief place of his reſidence, after being exiled from his native city, Reggio, was by ſome thought to have been a pupil of Correggio, by others of Michael Angelo, becauſe he was contemporary of both, and had ſomething of either in his ſtyle and colour. Little remains of his works, except ſome freſcoes in the ducal palace of Modena, and a copy of the Notte by Correggio, which is preſerved in the palace Gazzola at Verona. He was born in 1511, and died at the age of 76.

Orsi, Francis Joseph Augustine, a learned Italian cardinal, was born in Tuſcany in 1692. In early life he embraced the monaſtic ſtate in the Dominican order, and applied with ſuch ſucceſs to his ſtudies, that he was ſelected to fill

the chair of theological profeſſor. He was afterwards appointed maſter of the ſacred palace, and at length was promoted to the high dignity of cardinal, by pope Clement XIII., in 1759. In this ſituation he was diſtinguiſhed for modeſty and ſimplicity of manners, and his attention was entirely occupied by his ſtudies, and his zeal for the honour of the church. He died in 1761. He was author of "Infallibilitas Act. Rom. Pontificis," in three vols. 4to., but he is chiefly known to poſterity by his "Eccleſiaſtical Hiſtory," in twenty vols. This work is ſaid to be well written, but is by much too diffuſive: it is in the Italian language.

ORSIERRE, in *Geography*, a town of the Valais; 5 miles S. of Martigny.

ORSINI, Fulvio, in *Biography*, an eminent ſcholar, was born at Rome in 1530. Being an illegitimate child, his education would have been neglected, owing to the diſſentions of his parents, had not the quickneſs of his parts been noticed by a canon of the Lateran, (ſee Lateran,) who took him under his protection, and inſtructed him in claſſical literature. On arriving at years of diſcretion he entered ſucceſſively into the ſervice of ſeveral cardinals of high note, by which means an opportunity was afforded him of collecting a great number of books, eſpecially of ancient manuſcripts, and employing them for the benefit of literature. He was in habits of correſpondence with the moſt eminent literary characters of Italy, and he contributed much valuable aſſiſtance to the authors of that period. He had attained to great ſkill in diſcovering the antiquity and value of MSS., of which he was exceſſively proud. Cardinal Frederic Borromeo, being once in his company, requeſted Orſini to point out from a book that lay before them, the rules by which he diſtinguiſhed ancient from modern manuſcripts; upon this he immediately ſhut the book, and turned the diſcourſe. He died at Rome in the year 1600, at the age of 70: he was author of ſeveral learned works, as "De Familiis Romanis;" and an Appendix to Ciaconio's treatiſe "De Triclinio." He cauſed engravings to be made of a large collection of ſtatues, buſts, and other monuments of antiquity, and publiſhed them under the title of "Imagines et Elogia Virorum illuſtrium et eruditorum ex antiquis lapidibus et numiſmatibus expreſſa, cum annotationibus Fulvii Urſini." In order to keep together the books which, with great labour and at vaſt expence he had accumulated, he bequeathed them to the Vatican. He is ſtyled by De Thou, one of his eulogiſts, "Purioris antiquitatis indagator dilligentiſſimus."

Orsini, Gaetano, an Italian vocal performer of the early part of the laſt century, with a counter-tenor voice. The late Joſ. Benda, firſt violin to Frederic II. king of Pruſſia, ſo remarkable for taſte and expreſſion on the violin, confeſſed to us in converſation at Berlin, that in 1723, being at Prague at only 15 years old, when the emperor Charles VI. was crowned king of Bohemia, the excellent ſinging which he then heard was of the utmoſt uſe to him in his ſubſequent ſtudies, and particularly the performance of Gaetano Orſini, a contralto, with which he was beyond meaſure affected.

ORSIO, in *Geography*, a town of Sweden, in the province of Smaland; 20 miles W. of Calmar.

ORSKAIA, a town of Ruſſia in the government of Upha, on the Ural; 132 miles E. of Orenburg.

ORSKAR, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 60° 32′. E. long. 18° 11′.

ORSOGNA, a town of Naples, in Abruzzo Citra; 9 miles S.E. of Civita di Chieta.

ORSOKO, or Orsaki, a town of Africa, in the diſtrict of Acra, on the Gold Coaſt.

ORSOMORSO, a town of Naples, in Calabria Citra; 9 miles from Scalea.

ORSON's Island, an iſland in Penobſcot river, at the N. end of Marſh's iſland, containing about 1000 acres. This and Orono take their names from two Indian chiefs, their reſpective proprietors.

ORSOVA, or Orschowa, a fortreſs of Servia, built on both ſides of the Danube; the part on the left of the river, in the bannat of Temeſvar, is called Old Orſova, and was ceded to Auſtria by the peace of Siſtova; and that on the right bank of the river, called New Orſova, belongs to the Turks. This fortreſs was taken by general Laudohn, ſince which time it has been neglected; 75 miles E. of Belgrade. N. lat. 44° 55′. E. long. 21° 56′.

ORSOY, or Orsaw, a town of France, in the department of the Roer, lately belonging to the duchy of Cleves, on the Rhine; 24 miles S.E. of Cleves. N. lat. 51° 38′. E. long. 6° 35′.

ORT, Leer-Ort, or *Oort*, a town of Eaſt Frieſland, at the conflux of the Leer and the Ems; 11 miles S.S.E. of Emden. N. lat. 43° 13′. E. long. 7° 20′.

ORTA, a town of the Patrimonio, on the Tyber, once the ſee of a biſhop, now united to Civita Caſtellana; 12 miles E.N.E. of Viterbo.—Alſo, a town of Italy, in the department of the Gogna, on a lake to which it gives name; 36 miles W.N.W. of Milan.—Alſo, a town of Spain, in Catalonia; 12 miles N.W. of Tortoſa.—Alſo, a town of Naples, in the province of Capitanata; 11 miles N.N.E. of Aſcoli.

ORTAKI, a town of Aſiatic Turkey, in Natolia; 30 miles S.E. of Scala-nova.

OR-TCHELOSCHVEI, a town of Ruſſia, in the government of Kolivan; 16 miles S.E. of Mungatzkoi.

ORTEGAL, a ſmall town of Spain, in Galicia, near cape Ortegal; 13 miles from Corunna.

Ortegal, *Cape*, a cape on the N.W. coaſt of Spain, in the Atlantic ocean. N. lat. 43° 46′. W. long. 7° 55′. This is the extreme point of Spain, or the moſt advanced to the north of this coaſt: it forms a ſection between the Cantabrian ſea and the Atlantic ocean.

ORTEGIA, in *Botany*, a genus, named by Lœfling in honour of the friend and companion of his travels Joſeph Ortega, whoſe nephew Don Caſimiro Gomez de Ortega, M.D. F.R. and L.S. is the preſent profeſſor of Botany at Madrid. Among the publications of this gentleman, which conſiſt of ſeveral botanical tracts, is an account of the plants growing in the Royal Gardens at Madrid, publiſhed in numbers.—Lœfl. It. 112. Linn. Gen. 24. Schreb. 38. Willd. Sp. Pl. v. 1. 190. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 79. Juſſ. 299. Lamarck Dict. v. 4. 635. Illuſtr. t. 29. Gærtn. t. 129.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Caryophylleæ*, Linn. and Juſſ.

Gen. Ch. *Cal.* Perianth inferior, erect, permanent, of five oval leaves, membranous at their margins. *Cor.* none. *Stam.* Filaments three, awl-ſhaped, ſhorter than the calyx; anthers linear, compreſſed, ſhorter than the filaments. *Piſt.* Germen ſuperior, ovate, triangular at the top; ſtyle thread-ſhaped, almoſt as long as the calyx; ſtigma an obtuſe head. *Peric.* Capſule ovate, triangular in the upper part, of one cell, and three valves at the top. *Seeds* many, very ſmall, oblong, acute at each end.

Eſſ. Ch. Calyx of five leaves. Corolla none. Capſule of one cell. Seeds numerous.

Obſ. Lamarck obſerves that *Ortegia* is chiefly diſtinguiſhed from *Polycarpon* and *Læflingia* becauſe it is deſtitute of a corolla.

I. O.

1. O. *hiſpanica.* Spaniſh Ortegia. Linn. Sp. Pl. 49. Cavan. Ic. v. 1. 35. t. 47. (Juncarica ſalmanticenſis; Cluſ. Hiſt. v. 2. 174.)—Stem ſquare, branched. Stalks many-flowered. Flowers axillary, ſolitary. This ſpecies was originally obſerved by Cluſius near Salamanca, where it ſtill grows, as well as in various other parts of Spain, flowering in ſummer.—*Root* perennial? round, with branched fibres at the lower part. *Stems* numerous, about a foot long, jointed; the *branches* oppoſite, croſſing each other. *Leaves* oppoſite, ſeſſile, nearly linear, erect, bright green. *Flowers* herbaceous, minute, on ſhort ſtalks, ſo cloſe together as to reſemble a little head.

2. O. *dichotoma.* Forked Ortegia. Willd. n. 2. Allion. Pedem. v. 2. 210. Miſcell. Taurin. v. 3. 176. t. 4. f. 1.—Stem forked, angular. Stalks ſingle-flowered.—Native of Piedmont, and other parts of Italy. It flowers in Auguſt and September. *Root* perennial. *Stem* erect, jointed, ſtraight, roughiſh, furrowed at each end, thickiſh at the joints. *Leaves* oppoſite, linear, ſpreading, by no means ſmooth at the back. *Stipulas* two, between each pair of leaves, minute, briſtle-ſhaped, with a thickiſh, coloured baſe. *Flowers* in forked panicles, of a green colour. The habit of this ſpecies greatly reſembles that of a *Galium*, whilſt its ſtructure is very near that of a *Polycarpon*.

ORTEIL, in *Fortification.* See BERME.

ORTELIUS, ABRAHAM, in *Biography*, a celebrated geographer in the ſixteenth century, was born at Antwerp in the year 1527. He enjoyed the advantage of a good education, and as he had a ſtrong inclination for literature, he made a rapid progreſs in his ſtudies, and particularly excelled in the knowledge of the languages and in mathematics. So great was his ſkill in geographical ſcience, that he obtained the name of the "Ptolemy of the age." With a view to improve himſelf in his favourite ſtudy he travelled into England, Ireland, France, Italy, and Germany, directing his enquiries to every object that was worthy of his attention, and forming a correſpondence and friendſhip with men of learning and ſcience in thoſe countries. He viſited Italy three times, and ſpent ſome time at Oxford in the reign of king Edward VI. In England he formed an intimacy with William Camden, who, at his requeſt, as we are informed in the preface to the work, was engaged to undertake his Britannia. Having furniſhed himſelf with ample ſtores of geographical knowledge, Ortelius ſettled at Antwerp, where, in the year 1570, he publiſhed his "Theatrum Orbis Terrarum," which conſiſted of maps, accompanied with ſhort deſcriptions of the ſeveral countries, and the objects in them particularly intereſting to curioſity. This was the moſt complete work that had ever appeared, and it obtained the author a high reputation: he was almoſt immediately appointed to the poſt of geographer to Philip II. king of Spain. In the various editions called for, it underwent great improvements and enlargements, and in its moſt perfect ſtate, it was publiſhed by John Baptiſt Urientius, in Latin, Spaniſh, and Italian. An epitome or abridgment of this work was publiſhed by Michael Coignet from the Plantin preſs. Ortelius likewiſe publiſhed ſeveral geographical works; among which was one entitled "Synonima Geographica," being a kind of geographical dictionary, containing ſhort deſcriptions, in alphabetical order, of all the countries in the world, the mountains in thoſe countries, iſlands, cities, towns, &c. This work was afterwards greatly enlarged and publiſhed under the title of "Theſaurus Geographicus." In 1584 he publiſhed "Itinerarium per nonnullas Galliæ-Belgicæ partes, Abrahami Ortelli et Joannes Viviani," with engravings; and in 1598 appeared "Aurei Sæculi Imago," containing a deſcription of the manners and religion of the Germans, with illuſtrative plates. Ortelius had collected into a muſeum a conſiderable collection of ancient ſtatues, medals, &c. from which Francis Sweert publiſhed "Deorum, Dearumque Capita," and from the manuſcripts which he left behind him, was publiſhed "Syntagma Herbarum Encomiaſticum." Ortelius died at Antwerp in 1598, in the 71ſt year of his age. Moreri.

ORTELSBURG, in *Geography*, a town of Pruſſia, in the province of Oberland; 68 miles N. of Konigſberg. N. lat. 53° 23′. E. long. 20° 58′.

ORTENAU, a tract of Germany, included between the Briſgau, the marquiſate of Baden, the Black Foreſt, and the Rhine, which, in the diſpoſition of indemnities in 1802, after the peace of Luneville, was adjudged, together with the Briſgau, to the duke of Modena, and ſubſequently to the duke of Baden.

ORTENBERG, a town of Germany, in the county of Hanau Munzenburg, on the Nidder; 17 miles N E. of Frankfort on the Maine.

ORTENBURG, a town and citadel of Bavaria, which gives name to a county. The count and inhabitants are Lutherans; 10 miles W. of Paſſau.—Alſo, a town and citadel of Carinthia, on the Drave; 32 miles W. of Clagenfurt.—Alſo, a town of Germany, in the Ortenau; two miles S.E. of Offenburg.

ORTH, a town of Auſtria; eight miles E. of Entzerſtorff.

ORTHE'S, a town of France, and principal place of a diſtrict, in the department of the Lower Pyrenées; 30 miles E. of Bayonne. The place contains 6738, and the canton 14,032 inhabitants, on a territory of 192½ kiliometres, in 13 communes. N. lat. 43° 29′. W. long. 0° 42′.

ORTHIA, in *Ancient Geography*, a canton of the Peloponneſus, in Arcadia.

ORTHIA, in *Mythology*, the ſurname of Diana, who had a temple at Lacedæmon.

ORTHIAN. The Orthian nome, in *Greek Muſic*, was a dactylic nome, invented, according to ſome, by old Olympus the Phrygian, and according to others by the Myſian. It was in ſinging this Orthian nome, ſay Herodotus and Aulus Gellius, that Arion precipitated himſelf into the ſea.

ORTHOCERAS, in *Botany*, from ορθος, *ſtraight*, and κερας, *a horn*, a genus of *Orchideæ*, ſeparated by Mr. Brown, Prodr. Nov. Holl. v. 1. 316 from *Diuris*, on account of the more ringent *flower*, whoſe two lower calyx-leaves are ſtraight and its petals diminutive and cohering. The only ſpecies is

O. *ſtrictum*, a native of Port Jackſon, New South Wales. The *bulbs* are undivided. We are inclined to refer this plant to DIURIS; ſee that article.

ORTHOCERATITES, in *Natural Hiſtory*, a name by which ſome authors have called a ſpecies of ſea-ſhell, found frequently foſſile, but not known at preſent in its recent ſtate; called by others polythalamium, and tubulus marinus concameratus. It is uſually ſtraight, but ſometimes its end is twiſted like the cornu ammonis. See TUBULI *Concamerati*.

ORTHOCOLON, from ορθος, *ſtraight*, and κωλον, *a limb*. See ANCHYLOSIS.

ORTHODORON, ορθοδωρον, an ancient Greek long meaſure; being the ſpace from the carpus, or wriſt, to the tips of the fingers, rated at eleven inches.

ORTHODOXY, formed from ορθος, *right*, and δοξα, *opinion, judgment*, a ſoundneſs of doctrine or belief, with regard to all the points and articles of faith.

According to the proper etymology of the word, orthodoxy

doxy denotes what every honeſt man believes his own opinions to be, in contradiſtinction to the opinions of others, which he rejects. In England it is vulgarly reſtricted to ſignify the opinions contained in the thirty-nine articles; and in Scotland, it is in like manner uſed to denote the doctrines contained in their confeſſion of faith. It is, in general, applied to the opinions that are maintained by thoſe called Calviniſts.

Orthodoxy is uſed in oppoſition to *heterodoxy*, or *hereſy*.

ORTHODOXY, or *Feaſt of Orthodoxy*, denotes a ſolemn feaſt in the Greek church, inſtituted by the empreſs Theodora; ſtill held on the firſt Sunday in Lent, in memory of the reſtoration of images in churches, which had been taken down by the Iconoclaſts.

ORTHODROMICS, that part of navigation which teaches the art of ſailing in the arc of ſome great circle.

The word is Greek, ορθοδρομικα, derived from ορθος, *rectus*, *ſtraight*, and δρομος, *curſus*, *run*, or *diſtance*; *q. d.* the ſtraight or ſhorteſt diſtance; and this can only be in the arc of a great circle.

ORTHOEPY, formed of ορθος, *right*, and επος, *word*, in *Grammar*, denotes the juſt utterance of words. For pronunciation the beſt rule is, ſays Dr. Johnſon, to conſider thoſe as the moſt elegant ſpeakers, who deviate leaſt from the written words. See PRONUNCIATION.

ORTHOGONIAL, ORTHOGONIUS, in *Geometry*, denotes as much as rectangular or right-angled.

When the term is referred to a plain figure, it ſuppoſes one leg or ſide to ſtand perpendicular to the other: when ſpoken of ſolids, it ſuppoſes their axis to be perpendicular to the plane of the horizon.

ORTHOGRAPHIC *Projection of the Sphere*. See PROJECTION.

ORTHOGRAPHY, formed from ορθος, *right*, and γραφη, *writing*, in *Grammar*, the art of ſpelling; that is, writing words juſtly, and with all the proper and neceſſary letters. Or it is the art of combining letters into ſyllables, and ſyllables into words: or, more generally, it teaches the nature and powers of letters, or the form and ſound of letters, and the juſt method of ſpelling words. Accordingly orthography makes one of the four principal diviſions or branches of grammar: the other three being *etymology*, *ſyntax*, and *proſody*; which ſee reſpectively. Orthography, conſidered as the art of expreſſing certain ſounds by proper characters, may be ſuppoſed to include *orthoepy*; which ſee.

That diverſity found in moſt of the modern languages, eſpecially the Engliſh and French, between the pronunciation and orthography, makes one of the principal difficulties in acquiring them; nevertheleſs it ariſes from the ſame ſource as the languages themſelves.

The Gauls, *e. gr.* forming a new language from the ancient Latin, took the liberty to model the words to their fancy: at firſt, indeed, it is probable they wrote as they pronounced; but, by degrees, finding that words pronounced with all their letters ſounded harſh, they began to pronounce more ſmoothly.

Thus, in ſpeaking, they thought fit to ſoften that harſhneſs reſulting from the concurrence and claſhing of conſonants; but as the orthography, or writing, did not offend the ear, it ſtill continued on its former footing.

Attempts have been ſincē made to reduce the writing to that pronunciation, or to make us write as we ſpeak; which has occaſioned great diſputes. Pelletier of Mans was the firſt who pleaded for the change of orthography; and after him Maigret, Peter Ramus, De Bois, Menage, and others; but in vain.

They have, however, occaſioned a ſchiſm among writers, which has done more harm than the evil they intended to reform, the French writers being ſince divided into two parties; one of which adheres to the *old*, the other to the *new* orthography. The latter, F. Buffier obſerves, is the moſt conſiderable body; yet are theſe divided among themſelves, ſome being for carrying the reformation much farther than others.

The chief matters urged in behalf of the ancient orthography are, that by changing it we ſhould loſe ſight of the origin and etymology of words borrowed from the Greek and Latin, &c. That it does not matter what characters are uſed to expreſs ſounds in writing, provided one knows the relation between thoſe characters and the ſounds they repreſent; that by a neceſſary conſequence of ſuch change, the language would, in time, be all altered, and we ſhould loſe the uſe of our old authors; as ours, in their turn, would likewiſe become unintelligible.

What is alleged for the new orthography is, its being more commodious, natural, eaſy, ſhort, &c.

Some authors take a middle courſe between the two extremes, retrenching the letters where they are abſolutely uſeleſs, as the *s* in a multitude of words; and yet ſtudiouſly retaining all the letters on which the etymology has any dependence.

In the Engliſh, the orthography is more vague and unaſcertained than in any other language with which we are acquainted. Every author, and almoſt every printer, has his particular ſyſtem; nay, it is ſcarcely ſo well with us as that: we not only differ from one another, but there is ſcarcely any one that is conſiſtent with himſelf. The ſame word ſhall frequently appear with two or three different faces in the ſame page, not to ſay line. See ENGLISH.

Many ſchemes have been propoſed for the emendation and ſettlement of the Engliſh orthography, which, like that of other nations, being formed by chance, or according to the fancy of the earlieſt writers in rude ages, was at firſt very various and uncertain, and is yet ſufficiently irregular. Of theſe reformers, ſays Dr. Johnſon, ſome have endeavoured to accommodate orthography better to the pronunciation, without conſidering that this is to meaſure by a ſhadow, to that for a model or ſtandard which is changing while they apply it. Others, leſs abſurdly indeed, but with equal unlikelihood of ſucceſs, have endeavoured to proportion the number of letters to that of ſounds, that every ſound may have its own character, and every character a ſingle ſound. Such would be the orthography of a new language to be formed by a ſynod of grammarians upon principles of ſcience. But who can hope to prevail on nations to change their practice, and make all their old books uſeleſs? Or what advantage would a new orthography procure equivalent to the confuſion and perplexity of ſuch an alteration? Some of theſe ſchemes are exhibited by our learned lexicographer, which, he ſays, may be uſed according to the diverſities of genius, as a guide to reformers, or terror to innovators. One of the firſt who propoſed a ſcheme of regular orthography was ſir Thomas Smith, ſecretary of ſtate to queen Elizabeth, a man of real learning, and much practiſed in grammatical diſquiſitions. After him another mode of writing was offered by Dr. Gill, the celebrated maſter of St. Paul's ſchool in London. Dr. Gill, in his work entitled "Nature and Properties of Bees, 1634," was followed by Charles Butler, a man who did not want an underſtanding which qualified him for better employment. In the time of Charles I., there was a very prevalent inclination to change the orthography: as appears, among other books, in ſuch editions of the works of Milton as were publiſhed by himſelf. Of theſe reformers, every man had his own

ſcheme: but they agreed in one general deſign of accommodating the letters to the pronunciation, by ejecting ſuch as they thought ſuperfluous. Some of them would have written theſe lines thus:

"——————— All the erth
Shall then be paridis, far happier place
Than this of Eden, and far happier dais."

Biſhop Wilkins afterwards, in his great work of the philoſophical language, propoſed, without expecting to be followed, a regular orthography, by which the Lord's prayer is to be written thus:

"Yŭr Fâdher hŭitſh art in héven halloëd bi dhyi nám, dhyi cingdỳm cỳm, dhy will bi dỳn in erth az it iz in héven, &c."

We have ſince had no general reformers; but ſome ingenious men have endeavoured to deſerve well of their country, by writing *honor* and *labor*, for *honour* and *labour*, *red* for *read* in the preter tenſe, *ſais* for *ſays*, *repete* for *repeat*, *explane* for *explain*, and *declame* for *declaim*. Of theſe it may be ſaid, that as they have done no good, they have done little harm; both becauſe they have innovated little, and becauſe few have followed them.

A popular grammarian, after obſerving that the orthography of the Engliſh language is attended with much uncertainty and perplexity, ſuggeſts, that a conſiderable part of this inconvenience may be remedied, by attending to the general laws of formation; and for this end he preſents the reader with a view of ſuch general maxims, in ſpelling primitive and derivative words, as have been almoſt univerſally received. But as his valuable work is in almoſt every one's hands, we ſhall content ourſelves with referring to it. See Murray's Engliſh Grammar, ed. 2. 1809, vol. i. p. 56, &c.

The orthography of a great number of Engliſh words is very far from being fixed and uniform even among writers of diſtinction and in the beſt modern publications. It would therefore be extremely deſirable to have a generally approved and authoritative ſtandard, which might ſerve as a directory to the doubtful, and as a kind of teſt for deciding differences that occur in this department of grammar. The celebrated dictionary of Dr. Johnſon has occupied, and not without a very general conceſſion, this diſtinguiſhed rank in literature; and yet ſome few of his deciſions appear to be unwarranted by the principles of etymology and analogy. Of this dictionary, Dr. Nares, in his "Elements of Orthoepy," expreſſes a very high opinion, obſerving, that it has nearly fixed the external form of our language. He adds, "indeed, ſo convenient is it to have one acknowleged ſtandard to recur to; ſo much preferable, in matters of this nature, is a trifling degree of irregularity, to a continued change, and fruitleſs purſuit of unattainable perfection; that it is earneſtly to be hoped, that no author will henceforth, on light grounds, be tempted to innovate." Nevertheleſs, Mr. L. Murray has very juſtly obſerved, that this dictionary contains ſome orthographical inconſiſtencies, that ought to be rectified; and that if theſe, and ſimilar irregularities, were corrected, by ſpelling the words analogically, according to the firſt word in each part of the ſeries, and agreeably to the general rules of ſpelling, the dictionary would doubtleſs, in theſe reſpects, be improved. Such a work, on the plan of that of Dr. Johnſon, with neceſſary corrections and additions, is one of the deſiderata in Engliſh literature; and it is much to be regretted, that the undertaking has not yet been duly encouraged.

The ancients, who have written treatiſes of orthography, are Velius Longus, Marius Victorinus, Flavius Caper, Caſſiodorus, and Beda. Among the moderns, Torelli, Lipſius, Dauſquius, Scoppa, Valla, and Manutius the younger, have treated on the ſame ſubject.

ORTHOGRAPHY, in *Geometry*, is the art of drawing, or delineating the fore-right plan or ſide of any object, and of expreſſing the heights or elevations of each part.

It is called orthography, from the Greek ορθος, *right*, and γραφη, *deſcription*, from its determining things by perpendicular right lines falling on the geometrical plan; or rather, becauſe all the horizontal lines are here ſtraight and parallel, and not oblique, as in repreſentations of perſpective.

ORTHOGRAPHY, in *Architecture*, is the elevation of a building, ſhewing all the parts thereof in their true proportion. The orthography is either *external* or *internal*.

ORTHOGRAPHY, *External*, is a delineation of the outer face or front of a building, exhibiting the principal wall, with its apertures, roof, ornaments, and every thing viſible to an eye placed before the building.

ORTHOGRAPHY, *Internal*, called alſo *ſection*, is a delineation, or draught of a building, ſuch as it would appear, were the external wall removed. See PERSPECTIVE.

ORTHOGRAPHY, in *Fortification*, is the profile, or repreſentation of a work; or a draught ſo conducted, as that the length, breadth, height, and thickneſs, of the ſeveral parts are expreſſed; ſuch as they would appear, if it were perpendicularly cut from top to bottom.

ORTHONA, in *Mythology*, a divinity worſhipped at Athens, in the manner of that of Priapus.

ORTHOPNŒA, in *Medicine*, compounded of ορθος, *ſtraight*, *erect*, and πνεω, *I breathe*, ſignifies that extreme difficulty of reſpiration, which compels the patient to ſit upright in order to be able to perform the function of breathing. Orthopnœa, therefore, is not a diſtinct diſeaſe, but merely an extreme ſtate of *dyſpnœa*, and a ſymptom of ſeveral different diſeaſes.

The reaſon why the erect poſture is choſen, or becomes neceſſary in certain caſes of extreme difficulty of breathing, will be obvious, if we attend to the mechaniſm of reſpiration, and to the circumſtances under which orthopnœa occurs. The lungs occupy and completely fill (in a ſtate of health) the cavity of the cheſt, which is bounded by a caſe of bone (the ribs) and muſcle, and ſeparated from the belly, internally, by a muſcular curtain (the diaphragm). Now the act of breathing is performed by the enlargement of this cavity, when the external air immediately paſſes in, by the wind-pipe, to ſupply the vacuum, that would otherwiſe be produced; and this enlargement or expanſion of the cavity is effected partly by the elevation of the ribs, which move outwards as well as upwards, and partly by the contraction of the arch of the diaphragm downwards. In ordinary health, we can breathe by either of theſe modes; for it is not neceſſary to diſtend the lungs completely at each reſpiration. But when, from any cauſe, the acceſs of air into the lungs in ſufficient quantity is impeded, it then becomes neceſſary to employ every means of expanding the thorax, and obtaining a ſufficiency of the vital fluid. Now it muſt be obvious, that, in a ſupine poſture, not only the free motion of the ribs, on which the patient lies, but alſo the deſcent of the diaphragm, will be impeded, by the preſſure of the abdominal viſcera againſt it; ſo that if, with all the mechanical circumſtances in his favour, he is unable to obtain a ſufficient portion of air to carry on the function of the lungs, he will neceſſarily be reduced to extreme diſtreſs, when that ſupply is farther diminiſhed by the mechanical diſadvantages of a recumbent poſition; and he will, therefore, be compelled to aſſume the erect poſture, in which

which the gravity of the abdominal viſcera will aſſiſt the deſcent of the diaphragm, and the motion of the ribs will be free.

Orthopnœa is produced in the manner juſt deſcribed under all circumſtances, which greatly impede the act of reſpiration: theſe are, for inſtance, peripneumony, or inflammation of the lungs, eſpecially when that diſeaſe is ſevere and dangerous; ſpaſmodic aſthma, while the paroxyſm laſts, and the bronchial paſſages are contracted; the humoral aſthma, as it has been called, in which the cells and tubes are obſtructed by a congeſtion of mucus; and empyema, or abſceſs in the lungs, dropſy in the cheſt, tumours, and every other ſource of diminution of the cavity of the thorax. In ſome of the circumſtances laſt mentioned, namely, when a fluid is effuſed into the cavity of the cheſt, *i. e.* between the lungs and the *parietes* of that cavity, there is an additional reaſon for the occurrence of orthopnœa. When an abſceſs of the lungs breaks, and diſcharges its matter into the cavity, when the lungs are wounded, and blood is diſcharged in like manner, or when water is effuſed into the ſac of the *pleura*, theſe fluids neceſſarily gravitate to the moſt depending part, and therefore, when the body is in a ſupine poſition, they preſs upon the upper part of the lungs, and compreſs the bronchial paſſages; but, when the body is erect, they tend to preſs the diaphragm downwards, leaving the air-paſſages free, and conducing to the expanſion of the cavity.

One practical obſervation, deduced from theſe conſiderations, is of importance. An ordinary obſerver is liable to imagine, that a perſon, chooſing to ſit up, and ſhunning his bed, cannot be ſo ill as to be near death. But in the moſt acute peripneumony, it will ſometimes happen, that a patient will be found thus ſitting by the fire, within an hour or two of his deceaſe, becauſe he *cannot* lie down, a ſituation of the utmoſt danger. See PERIPNEUMONY, and DYSPNŒA.

ORTHOPOGON, in *Botany*, from ορθος, *ſtraight*, and πωγων, *a beard*, a genus of graſſes, eſtabliſhed by Mr. Brown, Prodr. Nov. Holl. v. 1. 194. It is diſtinguiſhed from *Panicum* merely on account of the nearly equal ſize of the calyx-valves, the outermoſt of which has a longer awn than the other; and more eſpecially on account of the ſmoothneſs or evenneſs of all the awns. The ſpecies are all tropical graſſes, growing in ſhady places. Their *leaves* flat and broadiſh. *Spike* compoſed of alternate ſpikelets, directed all one way, and ſometimes conſiſting of very few *flowers*. Four ſpecies are found in New Holland, *O. compoſitus*, *æmulus*, *flaccidus* and *imbecillis*. The firſt is *Panicum compoſitum* of Linnæus. Mr. Brown indicates two more graſſes as belonging to this genus, *P. hirtellum* of Linnæus, and *P. Burmanni* of Retzius. See PANICUM.

ORTHOSIA, or OR-TOSA, in *Geography*, a town of Syria, in the pachalic of Tripoli, on the coaſt of the Mediterranean; 12 miles N.E. of Tripoli. Conſiderable ruins indicate the ſcite of this ancient town, which was a place of conſequence, becauſe it commanded the paſs between Phœnicia and the maritime parts of Syria. It was ſituated to the right of the river Eleutherus, in the vicinity of that of Simyra. N. lat. 34° 47′. E. long. 35° 50′.

ORTHOSTEMON, in *Botany*, from ορθος, *ſtraight*, and στημων, *a ſtamen*. Brown Prodr. Nov. Holl. v. 1. 451.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Gentianæ*, Juſſ.

Eſſ. Ch. Calyx tubular, four-toothed. Corolla with a ſhort, deeply four-cleft limb, and naked mouth, withering. Stamens equal, prominent. Anthers burſting lengthwiſe, pointleſs, always ſtraight. Stigmas two, roundiſh.

A genus of flaccid *herbs*, with broadiſh *leaves*, and terminal *flowers*; which its author doubtfully ſeparates from *Canſcora* of Lamarck, and from his own *Erythræa*. This laſt includes the *Chironiæ* of Fl. Brit. though perhaps it may be properly ſeparated from the *Chironia* of Linnæus, an African ſhrubby genus.

ORTHOTRICHUM, from ορθος, *ſtraight* or *erect*, and θριξ, *a hair*, which appellation alludes to the hairs that, in moſt ſpecies, clothe the *calyptra* or veil in this very natural genus of moſſes, and whoſe erect poſition is directly the reverſe of what is obſervable in the hairy veil of *Polytrichum*. Hedw. Crypt. v. 2. 96. Swartz Act. Holm. for 1795. 247. Sm. Fl. Brit. 1262. Turn. Muſc. Hib. 92. Sims and Kon. Ann. of Bot. v. 2. 242. 532. (Weiſſia; Ehrh. Beitr. v. 1. 33. Schreb. 760.)—Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule oblong, terminal. Outer fringe of ſixteen teeth; inner of eight or ſixteen thread-ſhaped teeth, ſometimes wanting. Veil angular, moſtly clothed with erect hairs.

However natural this genus may be in habit, its character, as far as reſpects the inner fringe, is liable to the wideſt exceptions. Nor is the character of the hairy veil abſolutely conſtant, ſome ſpecies wanting that mark, though the ſtructure and aſpect of their veil are ſo preciſely ſimilar to others, which are hairy, that nothing ought to disjoin them. On the other hand, the genera of *Pterogonium* and *Neckera* have a veil often clothed with the erect hairs of *Orthotrichum*; but in theſe the fructification is axillary, and the veil cylindrical, not angular. The late Dr. Mohr, whoſe loſs cannot be too much lamented by cryptogamic botaniſts, has attempted to remove ſome of the difficulties above mentioned, by the eſtabliſhment of a new genus, called *Ulota*, from ουλος, *criſped*, which contains *Orthotrichum criſpum*, amongſt other ſpecies. In this he defines the veil as furniſhed with prominent ridges, whereas it has furrows in *Orthotrichum*. In the former the intermediate linear ſpaces are depreſſed channels, in the latter they are acute projecting edges or angles. The ridges of *Ulota* are often cloven at their baſe; ſo are the furrows of *Orthotrichum*, which proves their analogy. A tranſverſe ſection of either is a ſegment of a circle. (See ULOTA.) The teeth in the outer fringe of ſome genuine ſpecies of *Orthotrichum* are combined in pairs, but there is always a line of diſtinction to indicate this union, though to a ſlight obſerver the teeth may ſeem to be but eight.

Orthotrichum is divided into two ſections, the firſt comprehending ſuch ſpecies as have the proper double fringe of the genus; the ſecond ſuch as want the internal fringe.

Inſtances of the former are

O. *ſtriatum*. Common Briſtle-moſs. Hedw. Sp. Muſc. 163. Crypt. v. 2. 99. t. 36. Engl. Bot. 2187. (Bryum ſtriatum; Linn. Sp. Pl. 1579, α. Polytrichum ſtriatum; Hudſ. 471, α. P. bryi ruralis facie, capſulis ſeſſilibus, majus; Dill. Muſc. 430. t. 55. f. 8.)—Stem branched. Leaves lanceolate, keeled, revolute, ſpreading. Veil entire. Inner fringe of ſixteen teeth.—Not rare on the trunks of old trees, bearing capſules from February to May. Few ſpecies are ſo complete in the technical generic characters, for this has not only a hairy *veil*, but the outer fringe conſiſts of ſixteen diſtinct teeth, the inner of as many white, inflexed, linear, flat, jointed, jagged ones, more like ſcales than briſtles. The *ſtems* are perennial, tufted, branched, an inch or two high, clothed with crowded, ſpreading, lanceolate, acute, pointleſs, entire, revolute, ſingle-ribbed, dark-green *leaves*, the upper ones paleſt, more expanded, ſometimes jagged at the end. *Capſules* ſolitary, at the ends

of lateral ſhoots, projecting a little beyond the leaves, furrowed in the upper part when ripe, each on a very ſhort *fruit-ſtalk*. *Lid* ſhort, with a blunt, conical, ſhort point, cylindrical when dry, the edge crimſon. *Veil* partially covered with yellow vertical hairs. *Anthers* in axillary tufts, on a ſeparate plant.

O. *affine*. Pale Straight-leaved Briſtle-moſs. Schrad. Spicil. 67. Sm. Fl. Brit. n. 2. Engl. Bot. t. 1323. (Polytrichum capſulis ſeſſilibus, foliis brevibus rectis carinatis; Dill. Muſc. 432. t. 55. f. 10?)—Stem branched. Leaves lanceolate, keeled, revolute, ſpreading. Veil ſlightly crenate. Inner fringe of eight teeth.—More frequent perhaps than the foregoing, on rocks, old walls, cottage roofs, &c. It differs from that ſpecies in having paler *leaves*, a *fruit-ſtalk* more elongated as it grows older, *capſule* twiſted when ripe, but eſpecially an inner *fringe* of only eight teeth, or rather ſimple inflexed briſtles, not jointed except when very old.

O. *pulchellum*. Elegant Smooth Briſtle-moſs. Engl. Bot. t. 1787.—Stem ſomewhat branched. Leaves lanceolate, keeled, revolute, beardleſs, ſlightly twiſted when dry. Inner fringe of ſixteen briſtles. Capſule with eight furrows. Veil naked.—Found by Mr. Winch and Mr. Thornhill, on trees in various parts of the county of Durham, ſince the publication of Fl. Brit. The *ſtems* form tufts, not half an inch high. *Leaves* bright green, lanceolate, acute, beardleſs, ſingle-ribbed; ſlightly twiſted, not curled, by drying. *Fruit-ſtalks* elongated, conſpicuous above the leaves, twiſted and yellowiſh when full-grown. *Capſule* pale when ripe, with eight furrows, and as many intermediate ridges. Outer *fringe* of ſixteen elegant red teeth, partly combined in pairs; inner of ſixteen very ſlender pale briſtles, meeting by their points. *Veil* crenate at the baſe, deſtitute of hairs.

There are four more of this ſection natives of Britain, *O. pumilum*, Engl. Bot. t. 2168; *diaphanum*, t. 1324; *ariſtatum*, Turn. Muſc. Hib. t. 9. f. 2. (which is *diaphanum* of Dickſon); and *rivulare*, Engl. Bot. t. 2188. The three laſt have the full number of teeth to their inner *fringe*; the firſt has only eight. They all grow on trees or pales, and bear a general reſemblance to each other, except that *diaphanum* and *ariſtatum* have hoary points to their *leaves*.

O. *criſpum*, Fl. Brit. n 7. Engl. Bot. t. 996, belongs to the new genus *Ulota*, as above mentioned.

Species with a ſingle or outer fringe only, are

O. *anomalum*. Rough Single-fringed Briſtle-moſs. Hedw. Sp. Muſc. 162. Crypt. v. 2. 102. t. 37. Engl. Bot. t. 1423. (Bryum ſtriatum β; Linn. Sp. Pl. 1580. Polytrichum bryi ruralis facie, capſulis ſeſſilibus, minus; Dill. Muſc. 431. t. 55. f. 9. Weiſſia minor; Ehrh. Crypt. 282.)—Stem branched. Leaves lanceolate, keeled, revolute. Fringe ſimple. Veil hairy, toothed.—Common on rocks, ruins and ſtones, bearing fruit early in ſpring. The colour of the *leaves* is a dull browniſh-green, and their edges are revolute. Though this ſpecies has no internal *fringe*, its *veil* anſwers to the character and name of the genus better than ſome of the former, being very hairy, till it becomes bald by age.

O. *nudum*, Engl. Bot. t. 1325, found on poſts in ſhady places near rivers, is the only Britiſh ſpecies, of this ſection, beſides. This is of a very dark hue, and has no hairs upon the *veil*.

O. *Brownianum*, Fl. Brit. n. 10. (Grimmia Browniana; Engl. Bot. t. 1422), a minute and very curious moſs, is now found to have but four teeth to its fringe, which, in the ſpecimens Mr. Sowerby drew, was ſo imperfect as to miſlead his uſually very accurate obſervation. This plant therefore ranges in the genus TETRAPHIS; ſee that article hereafter, as well as FRINGES *of Moſſes*.

ORTHRAGORISCUS, in *Ichthyology*, the name uſed by Rondeletius, and ſome other authors, for the fiſh more commonly known by the name of the mola, and called in Engliſh the *ſun-fiſh*. See TETRODON *Mola*.

ORTI, in *Geography*, a town of Italy, in the Patrimonio, the ſee of a biſhop, united to Caſtellana; 12 miles E. of Viterbo.

ORTIBARIO, a town of the iſland of Corſica; 12 miles S. of Pellegrino.

ORTIEN, the Ortian nome, or air for a flute of a very acute tone, and full of life and fire; which by animating the combatants rendered it of great uſe in war.

ORTIGOSA, in *Geography*, a town of Spain, in Old Caſtile; 14 miles S. of Logrono.

ORTIVE, ORTIVUS, in *Aſtronomy*. *Ortive*, or *eaſtern amplitude*, is an arc of the horizon intercepted between the point where a ſtar riſes, and the eaſt point of the horizon, or point where the horizon and equator interſect. See AMPLITUDE.

ORTO, in *Geography*, a town of Chineſe Tartary; 50 miles W. of Hami. N. lat. 43° 46′. E. long. 92° 44′.

ORTOLAN, in *Ornithology*. See EMBERIZA.

ORTON, JOB, in *Biography*, an eminent nonconformiſt divine, was born at Shrewſbury in the year 1717, where he received part of his education, which was completed under the celebrated Dr. Doddridge at Northampton. He had ſcarcely finiſhed the courſe of his ſtudies, when he was appointed aſſiſtant tutor in the academy. In this capacity he paſſed ſome years, and then ſettled as diſſenting miniſter at Shrewſbury, his native town. He preached his firſt ſermon here in 1741, and was ordained in the following year, and ſo highly was he reſpected by his brethren, that thirty miniſters were preſent at the ſervice. In 1748 his health was ſo bad, that he was obliged to ſeek for an aſſiſtant to eaſe him of part of his labours. Mr. Fownes was the perſon fixed on, and with him Mr. Orton lived in the utmoſt harmony and friendſhip till the year 1765, when he reſigned the paſtoral office, and in the following year he removed to Kidderminſter, in order that he might benefit by the advice of Dr. Johnſtone, an able and ſkilful phyſician, who was alſo his intimate acquaintance and friend. Here Mr. Orton ſpent the remainder of his days zealouſly intent on promoting the intereſts of religion. What he could not perform as a preacher, he was ſolicitous to effect as a practical writer. His works are the "Life of Dr. Doddridge;" "Sermons to the Aged;" "Three Sermons on Eternity;" which are exceedingly impreſſive, and have been tranſlated into the Welſh language; "Three Sermons on Chriſtian Zeal;" "Three Sermons on Chriſtian Worſhip;" and ſome ſingle diſcourſes. Mr. Orton publiſhed alſo a volume of ſermons with the title of "Religious Exerciſes recommended, or Diſcourſes on the heavenly State, conſidered under the Idea of a Sabbath;" "Diſcourſes on Practical Subjects," in two vols.; "Sacramental Meditations, or, Devout Reflections on various Paſſages of Scripture, deſigned to aſſiſt Chriſtians in their Attendance on the Lord's Supper, and their immediate Improvement of it." This was his laſt publication. He died in the year 1783, and after his death was printed his "Practical Expoſition of the Old Teſtament," in ſix vols. 8vo, which probably did not anſwer the public expectations formed of it; and a ſmall collection of "Letters to a young Clergyman," which had been addreſſed to the Rev. Thomas Stedman, the editor, and which contained advice, that is, in general,

well adapted for the direction and improvement of the younger clergy of every denomination.

ORTON, or *Overton*, in *Geography*, a market town and parish in the East Ward, county of Westmoreland, England, is situated in a bleak, open country, at the distance of $9\frac{1}{2}$ miles S.W. by S. from Appleby, and $275\frac{3}{4}$ N.W. by N. from London. The town is of very trifling importance, and chiefly inhabited by farmers, engaged in the cultivation of the small tract of fertile ground by which it is immediately surrounded. The church here is a large, ancient edifice, with a tower at one end. Dr. Burn, author of "The Justice of the Peace," and one of the editors of the "History and Antiquities of Westmoreland and Cumberland," was vicar of Orton upwards of thirty years. Here are two free-schools. The market is held on Friday, every week, and there are two fairs during the year. According to the population returns of 1811, this parish contains 292 houses and 1333 inhabitants. A Topographical Description of Cumberland, Westmoreland, Lancashire, &c. by John Housman, 8vo. 1800.

ORTONA, in *Ancient Geography*, a town and port of Italy, in Samnium; it belonged to the people called Frentani, according to Strabo.

ORTONA *a Mare*, in *Geography*, a sea-port town of Naples, in Abruzzo Citra; the see of a bishop, united with Campali; 13 miles E. of Civita di Chieti. N. lat. 42° 20'. E. long. 14° 20'.

ORTORI, a town of Japan, in the island of Niphon; 15 miles S. of Idsami.

ORTOSTA, a town of Sweden, in the province of Schonen; five miles N. of Lund.

ORTRAND, a town of Saxony, in the margraviate of Meissen; 22 miles N. of Dresden.

ORTYGIA, in *Ancient Geography*, a small island on the E. coast of Sicily, before Syracuse, and at the mouth of the river Alpheus. Virgil mentions it in the Æneid, l. iii. v. 124. This island, on which Syracuse was founded and situated between its two ports, was always very important. See SYRACUSE.

ORTYGOMETRA, DAKER-HEN, in *Ornithology*. See RALLUS *Crax*.

ORVAL, in *Geography*, a town of France, in the department of the Forests; five miles N. of Montmedy.

ORVALA, or ORVALLA, in *Botany*, an old name for Clary, *Salvia Sclarea*, and other species of the same genus, adopted by Dodonæus. Linnæus applies it to a species of LAMIUM; see that article.

ORUBA, in *Geography*. See ARUBA.

ORUENNY, a town of Hindoostan, in Dowlatabad; 15 miles N.N.W. of Darore.

ORVIETA, *Penitents of*. See PENITENTS.

ORVIETAN, a celebrated antidote or counter-poison; so called, because invented, and originally sold, by an operator from Orvieta, in Italy, who made experiments of it on his own person, on the public stage, by taking several doses of poisons.

In Charas's Pharmacopeia is a method of making Orvietan; where it appears, that Venice treacle is one of the principal ingredients of it.

ORVIETO, in *Geography*, a city of Italy, and capital of a province, called the "Orvietan," the see of a bishop, situated at the conflux of the Paglia and the Chiana. The cathedral is a fine Gothic building, and contains some good sculptures and paintings. The country of Orvietan is about 20 miles long, and from 10 to 15 wide; 73 miles S.S.E. of Florence. N. lat. 42° 42'. E. long. 12° 3'.

ORVILLE, JAMES PHILIP D', in *Biography*, was born at Amsterdam in 1696, of a family originally from France. From early life he shewed an ardent attachment to letters, and afterwards travelled into various parts of Europe, visiting the libraries and cabinets and forming connections with learned men; and upon his return, in 1736, he was appointed professor of history, eloquence, and the Greek language at Amsterdam. The duties of this office he performed with high reputation about six years, when he resigned it, in order to devote himself wholly to study and literary composition. In conjunction with Burmann, he continued a work, which had been begun by some learned Englishmen, entitled "Observationes Miscellaneæ Novæ," and ten volumes of it were published by them jointly, and four others were published by d'Orville separately. Some pieces of his own writing are contained in this collection, among which are "A Dissertation on the Antiquity of the Isle of Delos," and "Remarks on the Greek Romance of Chariton." He was likewise author of a learned and severe critique upon Pauw of Utrecht. He died in 1751, and after his death were published his observations on Sicily under the title of "Siculæ." Gen. Biog.

ORUM, in *Geography*, a town of Denmark, in North Jutland; 11 miles S.W. of Tysted.

ORURILLO, a town of Peru, in the diocese of La Paz, on lake Titicaca; 25 miles N.W. of Asangaro.

ORURO, a jurisdiction of Peru, in the government of Buenos Ayres, and archbishopric of La Plata. The climate is cold, so that no vegetable will flourish; but its herds are numerous, and it has been long famous for its gold and silver mines. The former have not long since been wrought, and the latter have declined. Oruro, the capital, has, according to Alcedo, five convents and four parish churches.

ORUROS, GORUR, in *Ancient Geography*, a town of Asia, in Syria, on the banks of the Euphrates; S. of Auzara, and 250 miles from Zeugma. In the time of Pompey, it was on this side the boundary of the Roman empire.

ORUS, or HORUS, in *Mythology*, a famous deity of ancient Egypt, which, as well as Osiris, was an emblem of the sun. To this purpose Plutarch says, that virtue, which presides over the sun, whilst he is moving through space, the Egyptians called Horus, and the Greeks Apollo. The veneration in which this deity was held in Egypt appears from the circumstance of three cities having been called by this name in the Thebais. The sparrow-hawk was the common emblem of Osiris and Horus, and both had sometimes the same attribute. According to the interpretation of the hieroglyphics of Heliopolis, Horus is the supreme lord and the author of time, and this evinces the propriety of representing him as the star of the day, or the sun. The Egyptians describe him under the appellation of Horapollo, as borne on lions, thus signifying his entrance into the sign of the zodiac, called the lion. Macrobius, who informs us why the Greeks gave Horus the name of Apollo, confirms this sentiment: "In the mysteries," says he, (Saturn. lib. i.) "they discover us a secret, which ought to be inviolable, that the sun, arrived in the upper hemisphere, is called Apollo." Hence we may infer, that this emblematical deity was no other than the star of day, passing through the signs of summer. Plutarch, in his "Treatise of Isis and Osiris," gives us the principal traits of the history of Horus. Accordingly he is represented as the son of Osiris and Isis; and it is said, that Typhon, after killing his brother Osiris, took possession of the kingdom, and that Horus, leaguing himself with his mother Isis, avenged the death of his father, expelled the tyrant from his throne, without depriving him of

of life, and reigned gloriouſly in Egypt. Diodorus, who adopts the relation of Herodotus in theſe particulars, adds, that the Titans having put Horus to death, his mother, who poſſeſſed the moſt rare ſecrets in medicine, even that of making him immortal, having found his body in the Nile, whither they had thrown it, reſtored life to it, and procured for him immortality. After this, ſhe taught him medicine and the art of divination. With theſe talents, Orus rendered himſelf famous, and multiplied his bleſſings upon the world. As Apollo among the Greeks was called the Horus of the Egyptians, as to his ſkill both in medicine and divination, he was regarded as the ſame perſon, and called by the ancients Horus-Apollo. In all the figures of Horus which antiquity affords us in the Iſiac table, and other monuments, he is always repreſented as a child, thus intimating that he was very young when Typhon put his father to death, and that Iſis, his mother, was obliged to defer the puniſhment of the tyrant till her ſon was capable of being the inſtrument of her revenge. The allegory of Horus has been thus explained. The wind Khamſin makes great ravages in Egypt in the ſpring; by raiſing whirl-winds of burning ſands, which ſuffocate travellers, darken the air, and cover the face of the ſun, ſo as to leave the earth in perfect obſcurity. This circumſtance repreſents the death of Oſiris, and the reign of Typhon. When the ſun approaches the ſign of the lion, he changes the ſtate of the atmoſphere, diſperſes theſe tempeſts, and reſtores the northerly winds, which drive before them the malignant vapours, and preſerve in Egypt coolneſs and ſalubrity under a burning ſky. This is the triumph of Horus over Typhon, and his glorious reign. As ſome natural philoſophers have acknowledged the influence of the moon over the ſtate of the atmoſphere, they united her with this god to drive the uſurper from the throne. The prieſts conſidering Oſiris as the father of time, might beſtow the name of his ſon on Horus, who reigned three months in the year.

Jablonſki, who has interpreted the epithet of "Arueri," which the Egyptians gave to Horus, pretends that it ſignifies "efficacious virtue." Theſe expreſſions perfectly characteriſe the phenomena which happened during the reign of this god. It is in ſummer, in fact, that the ſun manifeſts all its power in Egypt. It is then that he ſwells the waters of the river with rains, exhaled by him in the air, and driven againſt the ſummit of the Abyſſinian mountains; it is then that the huſbandman reckons on the treaſures of agriculture. It was natural for them to honour him with the name of "Arueri," or efficacious virtue, to mark theſe auſpicious effects. Savary's Letters in Egypt, vol. ii. See Isis and Osiris.

ORWEL, in *Geography*, a poſt-town of America, in Vermont; the north-weſternmoſt in Rutland county, on the E. ſide of lake Champlain, containing 1376 inhabitants.

ORWELL, a river of Canada, which runs into lake Erie, N. lat. 43°. W. long. 80° 30′.—Alſo, a river of England, in the county of Suffolk, called "Ipſwich Water," which paſſes by Stow, Needham, Ipſwich, &c., and joining the Stour, forms the harbour of Harwich, called "Orwell Haven," and ſoon after diſcharges itſelf into the German ſea.

ORYCTOGNOSY, that branch of mineralogy, which has for its object the claſſification of minerals, after well aſcertained characters, and under appropriate and fixed denominations. It is the baſis of all the remaining doctrines of *mineralogy*; which ſee. As the various mineral ſubſtances are conſidered ſeparately in this work, we ſhall in the preſent article treat only on that eſſential part of this doctrine which makes us acquainted with the *characters* of minerals.

The characters employed in the deſcription of minerals are by Werner divided into five claſſes: 1. *External characters*, are thoſe which are diſcoverable by means of the external ſenſes, in the aggregation of foſſils. 2. *Chemical* or *internal characters*, are thoſe which are founded on the compoſition of the minerals, and are diſcovered by means of chemical agents and analyſis. 3. *Phyſical characters*, are thoſe which we derive from particular phyſical properties of foſſils, and which are obſerved in the relations that foſſils bear towards other ſubſtances. The moſt common of the phyſical characters is the property which ſome minerals poſſeſs of exhibiting ſigns of electricity and magnetiſm. Some minerals become electric by being heated, and others by friction; and the electricity thus excited is in ſome vitreous or poſitive, and in others reſinous or negative. Some minerals too, and particularly ſome varieties of iron ore, are diſtinguiſhed by being attracted by the magnet: ſuch are magnetic pyrites and magnetic iron ſand. By filing a mineral ſo fine, that the particles ſhall ſwim on water, and then applying a magnet, the ſlighteſt degree of magnetic effect may be obſerved. Among the phyſical properties of minerals, alſo, may be reckoned the phoſphoreſcence which is produced by friction, as in ſome varieties of blende; or by expoſure to heat, as fluor ſpar and ſome calcareous ſpars. To theſe characters alſo belongs the peculiar property of Lemnian earth, and ſome other boles, which being thrown into water ſplit into pieces with a crackling noiſe, and the property of ſome opals and other ſtones, of acquiring a higher degree of tranſparency when they are immerſed in water, hence called hydrophanes. 4. *Empirical characters*, are thoſe which, in forming an opinion of a foſſil, are deduced from the foſſils with which it is found, from the circumſtances under which it occurs, and from the place of its formation: theſe empirical characters are alſo known by the names of geognoſtic and geographic characters.

As the *external* characters, which conſtitute the chief ſubject of this article, are preſent in every ſpecies of foſſils, and in every individual; as they are derived from the diverſity in the aggregation, and are therefore indicative of the eſſential difference of foſſils; as they may, moreover, be accurately known and defined, and eaſily diſcovered, independently of the analyſis of foſſils; it is evident that they are the moſt eligible for the purpoſes of oryctognoſy. It is to the celebrated profeſſor of Freiberg that the world is indebted for a complete treatiſe on this ſubject. (Werner uber die äuſſern Kennzeichen der Foſſilien. Leipzig 1774.) In this important work the author has collected all the old and known characters, deſcribed many which he himſelf diſcovered, and given, together with accurate definitions, appropriate names to each of theſe characters, which are arranged by him in ſyſtematic order.

With regard to the arrangement of the external characters, it ſhould be obſerved that Werner divides them into *generic* and *ſpecific*: the former are certain properties of minerals uſed as characters, without any reference to their differences; ſuch as colour, luſtre, weight, &c. The differences among theſe properties form the ſpecific characters, ſuch as adamantine luſtre, vitreous luſtre, &c. The generic characters are divided into *general* and *particular*. Under the former are comprehended thoſe that occur in all minerals; under the latter, thoſe which occur only in particular claſſes of minerals. The particular generic characters are arranged according to the order in which they preſent themſelves to the ſenſes, as is exhibited in the following table.

TABLE of the Generic External Characters.

General Generic External Characters.

i. The colour.
ij. The cohesion of the particles, in relation to which fossils are distinguished into Solid, Friable, and Fluid.

		Particular generic Characters of *solid* Minerals.	Particular generic Characters of *friable* Minerals.	Particular generic Characters of *fluid* Minerals.
Characters for the Sight.	External aspect -	External shape.	External shape.	The lustre.
		External surface.		
		External lustre.

	v.	The weight.
For the smell	vi.	The smell.
For the taste	vii.	The taste.

General generic external Characters, with their subordinate specific Characters.

I. *The Colour.*—This is not only the most obvious, but in many cases also one of the most certain external characters, and even serves as the principal distinguishing mark of many mineral substances.

1. *Principal Colours.*—These are not derived from the division of the solar ray by means of the prism, but are such as are considered simple in common life. They are

White.—Snow-white; the purest white colour, as in quartz, white lead, Carrara marble:—reddish-white, as porcelain earth, calcareous spar from Andreasberg, brown spar:—yellowish-white; in white amber, zeolite:—silver-white; native silver, arsenical pyrites, mica:—greyish-white; common quartz, granular lime-stone:—greenish-white; amianth, talc, tremolite:—milk-white; common opal, fibrous amethyst:—tin-white; white cobalt ore, native antimony, native platina.

Grey—of which smoke-grey is the characteristic or principal variety: lead grey; as in galena, grey antimony, graphite:—blueish-grey; indurated marle, hornstone, clay-slate:—pearl-grey; horn silver, common quartz, porcelain jasper:—smoke-grey; flint hornstone, Bolognese spar:—greenish-grey; clay-slate, common jasper, mica, fullers'-earth:—yellowish-grey; iron spar, indurated marle, common clay iron-stone:—steel-grey, grey copper ore, radiated grey manganese ore:—ash-grey; basalt, wacke, some varieties of clay-slate.

Black.—Of this deep or velvet black is the purest variety:—greyish-black; basalt, black lime-stone, basaltic hornblende:—iron-black; magnetic iron sand, micaceous iron, glanz coal:—greenish or raven-black; serpentine, common hornblende, pitch-stone:—browniſh or pitch-black; black blende, tin-stone, bituminous slate:—dark or velvet black; obsidian, Lydian stone, common shorl:—blueish-black; black earthy cobalt, black lead ore.

Blue.—Of this the Prussian or Berlin blue is the characteristic, or purest variety. Indigo blue; blue iron earth, sapphire, a variety of tourmaline:—Prussian blue; radiated azure copper, sapphire, rock salt:—azure blue; lapis lazuli, earthy azure copper:—violet blue; fluor-spar, amethyst, apatite:—plum blue; spinel, axinite:—lavender blue; porcelain jasper, indurated Saxon lithomarge:—smalt blue; blue iron earth, azure copper:—sky blue; feldspar of Krieglach, turquoise.

Green.—The purest of its tints is emerald green. Verdigris green; copper green, iron vitriol, fluor-spar:—celadon green; green earth of Monte Baldo, noble beryl:—mountain green; noble beryl, hornstone, actinote:—emerald green; emerald, fluor, dioptase:—leek green; nephrite, prase, variety of tourmaline, augite:—apple green; chrysopras, nickel ochre:—grass green; uran mica, malachite, green lead ore:—blackish-green; serpentine, common chlorite, hornblende:—pistachio green; slaggy copper green of Salfeld, common garnet, chrysolite:—asparagus green; chrysoberyl, asparagus stone:—olive green; olive copper ore, olivine, common garnet:—oil green;

green; beryl, pitch-ſtone, green lead ore, fullers' earth:—ſiſkin green, green lead ore, uran mica, green iron earth.

Yellow.—Of this lemon yellow is the pureſt tint. Sulphur yellow; native ſulphur, yellow ſerpentine:—braſs yellow; copper pyrites, pale yellow native gold:—ſtraw yellow; calamine, yellow earthy cobalt:—bronze or bell-metal yellow; iron pyrites:—wax yellow; common opal, yellow lead ore:—honey yellow; honey ſtone or mellite, amber:—lemon yellow; yellow orpiment, ſome varieties of yellow lead ore:—gold yellow; deep yellow native gold, copper pyrites:—ochre yellow; yellow earth, calamine, ochrey brown iron-ſtone:—wine yellow; Saxon topaze, fluor-ſpar:—iſabel or cream yellow; iron ſpar, calamine, mountain cork:—orange yellow; realgar, red lead ore (chromate of lead).

Red.—Its pureſt variety is carmine red. Aurora red; a variety of realgar, blende from Scharfenberg:—hyacinth red; hyacinth, garnet:—tile red; tile ore, common clay, common jaſper:—ſcarlet red; light red cinnabar:—blood red; Bohemian garnet, light red ſilver ore, carnelian, common jaſper:—copper red; native copper:—carmine red; filiform red copper ore from Treves, bright red cinnabar:—fleſh red; feldſpar, brown ſpar, indurated lithomarge of Rochlitz:—cochineal red; dark red copper ore, dark red cinnabar:—crimſon red; noble garnet, amethyſt-ſapphire:—roſe red; roſe or milk quartz, red manganeſe ore, brown ſpar:—peach bloſſom red; cobalt bloom:—columbine red; noble garnet, red cobalt:—cherry red; red antimony from Braunſdorf, red iron-froth:—browniſh-red; common clay iron-ſtone, common jaſper.

Brown.—Its moſt intenſe variety is blackiſh-brown. Reddiſh-brown; tin-ſtone, brown blende:—clove brown; brown iron-ſtone, a variety of rock cryſtal:—hair brown; wood tin, wood opal:—broccoli brown; zircon:—cheſnut brown; Egyptian jaſper, opal jaſper:—yellowiſh-brown; common clay iron-ſtone, brown blende, cat's eye:—pinchbeck brown; magnetic pyrites, mica:—wood brown; mountain wood, bituminous wood, brown coal:—liver brown; brown earthy cobalt, ſemi-opal:—blackiſh-brown; mica, copper black, brown coal, &c.

2. *Shade or Intenſity of Colour.*—Colours may be determined by the relation in which they ſtand to each other, with regard to intenſity or ſhade. Thus, among the principal colours there are ſome which are light, ſuch as white and yellow; and ſome which are dark, as blue and black. And, beſides, the varieties of the principal colours differ from each other in reſpect to ſhade: thus, among the blue colours, indigo blue is dark, azure blue clear, and ſky blue light; and even the varieties may afford a diverſity of ſhade, as, for inſtance, clear ſiſkin green, light ſiſkin green. The peculiar ſhade of colour in a mineral is frequently owing to its greater or leſs tranſparency; the paleneſs being in proportion to the degree of tranſparency, and the darkneſs to the degree of opacity. The degree of luſtre, alſo, in minerals produces great variety in the ſhade of colour.

In diſcriminating the ſhade or intenſity of colour, four degrees have only in general been adopted, which are expreſſed by the words *dark*, *clear*, *light*, and *pale*.

3. *Tarniſhed Colours.*—By tarniſh is meant a difference in the colour of the ſurface, after expoſure to the air, from what the freſh fracture of the mineral exhibits. Some minerals are always found tarniſhed in their natural poſition in the earth, as is the caſe in common galena, grey antimony, and blende; ſome tarniſh on every freſh fracture being made, as in native arſenic and copper pyrites; while others are tarniſhed in both caſes, as in native arſenic and purple or variegated copper ore. The tarniſhed colours are divided into, (*a*), ſimple tarniſhed colours: *viz.* grey, as in white cobalt; black, as in native arſenic; brown, as in native ſilver, copper pyrites; reddiſh, as in native biſmuth; yellowiſh, as in white cobalt ore: and, (*b*), variegated tarniſhed colours, the varieties of which are pavonine or peacock-tail tarniſh, as in copper pyrites; irideſcent or rainbow tarniſh, as in galena; columbine or pigeon-neck tarniſh, as in biſmuth; and tempered ſteel tarniſh, as in ſpecular iron.

4. *The Play of Colours.*—By this is underſtood the property which ſome minerals poſſeſs of refracting from particular ſpots the different rays of light. The play of colours in a mineral can only be obſerved in ſun-ſhine, or in a ſtrong light. It is remarkable in the diamond, the rock cryſtal, &c.

5. *The mutable Reflection of Colour.*—This is diſtinguiſhed from the play of colours, by the mineral exhibiting in the ſame ſpot a change of colour, according to the poſition of its ſurface being varied, producing a different angle with the incident rays of light. This mutable reflection is either ſuperficial, as in Labrador ſtone; or internal, as in common opal, dichroite or iolite, &c.

6. *The Mutation of Colour.*—This is diſtinguiſhed from the tarniſh, in which latter the ſurface only undergoes a change of colour; but in the mutation of colour, the effect penetrates the mineral, and ſometimes pervades the whole. This affords two varieties: (*a*) the *fading* of colour, by which is meant, that the colour of a mineral becomes paler, when expoſed to the light and heat, or is undergoing decompoſition: thus ſtriated red cobalt, when expoſed to the air, becomes pale browniſh; chryſopraſe becomes light green, &c.: (*b*) the *perfect change* of colour is often the conſequence of fading, when one colour is loſt, and a new one appears, as in light coloured ſparry iron-ſtone, and earthy grey manganeſe.

7. *Delineations of Colours.*—Theſe are obſerved on ſimple minerals; the ſame ſpecimen containing ſeveral colours which paſs through its interior, according to certain delineations. Of theſe there are nine varieties: *viz.* dotted; when fine points of another colour are diſperſed over the ſurface, as in a variety of ſerpentine:—ſpotted; when the points or ſpots are from a quarter of an inch to one inch in diameter; they are either round and regular, or irregular:—nebulous or cloudy; when the ſpots are large and forming the appearance of clouds, as in common calcedony, carnelian, &c.:—flamy; when the ſpots are large and drawn in one direction to a ſharp point, as in a variety of common jaſper:—ſtriped; when narrower and broader ſtripes run parallel through the whole ſpecimen:—annular; when the ſtripes form concentric circles, as in flints:—dendritic; when the delineation reſembles the ramifications of a tree:—ruin-ſhaped; as in the Florentine marble:—veined; as in various marbles, ſerpentine, &c. Many of theſe ſeem to require no definition.

II. *The Coheſion of the Particles.*—According to this property, minerals are divided into ſolid, friable, and fluid; but theſe properties alſo belong to the particular generic characters of minerals, to be afterwards deſcribed.

Particular generic Characters of Solid Minerals.

1. *The external Aſpect.*—In the external appearance or aſpect of a mineral, three things are to be obſerved; the external ſhape, the external ſurface, and the external luſtre.

i. *The external Form.*—This is divided into common, particular, regular, and extraneous external form.

1. *Common external Form.*—Of this a mineral is ſaid to be when it exhibits no reſemblance to any known ſubſtance

in

in common life. There are ſix varieties of it: *viz.* maſſive; when a mineral is of an indeterminate form, or amorphous, or of nearly equal dimenſions, from the ſize of a hazel-nut to the greateſt magnitude: — diſſeminated; when a mineral, without any particular form, is in ſmall pieces, not exceeding the ſize of a hazel-nut, incorporated with another ſolid mineral; coarſely diſſeminated, implies the ſize of a hazel-nut to that of a pea; finely diſſeminated, is from the ſize of a pea to that of a grain of millet; and minutely diſſeminated, from the ſize of a grain of millet till it is ſcarcely perceptible to the eye:—in angular pieces; theſe are either ſharp cornered, as in calcedony and quartz, or blunt cornered, as in common opal:—in grains, which are either looſe or imbedded; they are called large, when they are from the ſize of a hazel-nut to that of a pea; coarſe, from the ſize of a pea to that of a hemp-ſeed; ſmall, from the ſize of a hemp-ſeed to that of a millet-ſeed; and according to their form they are divided into angular and rounded grains: —in plates; diſtinguiſhed into thick plates, as in red ſilver, and into thin plates, as in vitreous ſilver ore: —in membranes; theſe differ from the preceding in being ſtill thinner, not exceeding the thickneſs of common paper.

2. *Particular external Form.*—The forms which come under this denomination exhibit a greater or leſs reſemblance both to natural and artificial objects. They are called particular, becauſe, like the former, they are not uſual or common; they are alſo diſtinguiſhed by the appellation of imitative forms. There are five kinds of particular external forms: *viz.* elongated, rounded, flattened, impreſſed, and confuſed: (*a*) *elongated;* this form has eleven varieties, *viz.* dentiform, or tooth-ſhaped; native ſilver and vitreous ſilver:—filiform, or thread-ſhaped; native ſilver:—capillary, or hair-ſhaped, native gold and ſilver:—reticulated, or net-ſhaped; native ſilver and copper, and a variety of galena:—dendritic, or tree-ſhaped; native ſilver and gold: - coralloid, or branched; the ſhape of corals, as in the beautiful variety of arragonite called flos ferri:—ſtalactic, or ſtalactitic; calcareous ſinter, brown iron-ſtone, calcedony:—tubiform: —claviform, or club-ſhaped:—fruticoſe, or ſhrub-like; all theſe forms are obſervable in calcareous ſinter, brown hematite, and compact manganeſe ore: (*b*) *rounded;* of which there are five varieties, *viz.* globular; this is ſubdivided into perfectly globular, as in pea-ſtone; elliptical, as in quartz and flint; amygdaloid, as in zeolite; ſpheroidal, as in Egyptian jaſper and calcedony; and imperfectly globular, as in carnelian and calcedony:—botryoidal; reſembling a bunch of grapes, as in black cobalt ore, manganeſe:—reniform, or kidney-ſhaped; as in red hematite, native arſenic, and malachite:—tuberoſe, or knob-ſhaped; as in flint and menilite:—liquiform, or fuſed like melted lead; a rare variety of galena from Freiberg: (*c*) *flattened;* of this there are three varieties, *viz.* ſpecular; as in galena:—in laminæ, or leaves; as in native gold:—combed, or ſulcated; as in quartz from Schemnitz: (*d*) *impreſſed;* of which there are ſix varieties, *viz.* cellular; which is ſubdivided according as the cells are angular or circular:—with impreſſions; of theſe the cubic, the pyramidal, the conical, the tabular, and the globular are the moſt remarkable:—perforated; as in ſwampy iron ore: —corroded; as in quartz, galena, and vitreous ſilver:—amorphous; ſurface with irregular and indeterminable inequalities, as in ſwampy iron ore:—veſicular; as in lavas and pumice-ſtone: (*e*) *confuſed;* of which there is only one variety, *viz.* ramoſe; as native iron and vitreous ſilver.

3. *Regular external Forms or Cryſtallizations.*—In deſcribing cryſtallizations we have to conſider

A. *The eſſential Quality of the Cryſtals*, which is either genuine or ſpurious. Spurious or ſuppoſititious cryſtals are diſtinguiſhed from genuine or true cryſtals by being often hollow, having a rough or druſy ſurface, and the ſolid angles or edges never ſharp or well defined; examples are found in quartz of the ſpurious cryſtals of the cube and of the octahedron of fluor ſpar, &c.

B. *The Form of the Cryſtal.*—This is compoſed of planes; of edges formed by the junction of two planes; of plane angles; and of ſolid angles formed by the union of three or more planes in one point.

To determine the form of cryſtals it is neceſſary to define the fundamental figures, and then the ſeveral modifications of theſe forms.

a. The Parts of the fundamental Form are:—planes, which are either lateral or terminal; edges, which are alſo either lateral or terminal; and ſolid angles, which have been defined above.

b. Varieties of the fundamental Form.—They are the icoſahedron, which is compoſed of twenty equilateral triangular planes; as iron pyrites:—the dodecahedron, compoſed of twelve regular pentagonal planes that meet under obtuſe angles; as in iron pyrites and white cobalt: —the hexahedron, including the cube and the rhomb, compoſed of ſix quadrilateral planes; calcareous ſpar, fluor ſpar:—the priſm, conſiſting of an indeterminate number of quadrangular lateral planes, terminated by two planes parallel to each other, and having each as many ſides as the priſm has lateral planes; calcareous ſpar:—the pyramid, which is compoſed of an indeterminate number of triangular, lateral planes, converging to a point, and of a baſe having as many ſides as the figure has lateral planes; quartz, calcareous ſpar: —the table, which is compoſed of two lateral planes, equal and parallel, which are bounded by an indeterminate number of terminal planes; tabular barytes:—the lens, compoſed of two convex planes; ſparry iron-ſtone.

c. Differences in each fundamental Form.—Theſe fundamental forms differ from each other according to ſimplicity, number of planes, ſize of the planes, angles under which they meet, direction of the planes, and fullneſs of the cryſtal.

α. Simplicity.—This diſtinction is confined to the pyramid, which is either ſimple or double. The ſimple figure is alſo diſtinguiſhed in regard of its poſition, which is either erect or inverted: the latter, which adheres by its ſummit, is ſcarce; in the double figure the lateral planes of the one pyramid are ſet either on the lateral edges, or lateral planes of the other.

β. Number of Planes.—The number of planes in the icoſahedron, dodecahedron, hexahedron, and lens, is always determinate; but in the priſm, pyramid, and table, it is indeterminate. The priſm occurs with three, four, ſix, (more ſeldom with eight or nine), and twelve planes; the pyramid occurs with three, four, ſix, and eight ſides; the table has four, ſix, or eight terminal planes.

γ. The Size of the Planes in relation to each other—They are either equal or unequal, and, in the latter caſe, either indeterminately or determinately unequal: the varieties obſerved in the determinately unequal planes are the following; with planes alternately broad and narrow; with two oppoſite planes broader; and with two oppoſite planes narrower.

δ. Angles under which the Planes meet.—Theſe are angles of the lateral edges, of the terminal edges, and of the ſummit. *Angles of the lateral edges*: theſe are equiangular, as in the icoſahedron of iron pyrites; rectangular, as in galena; oblique angular, as in rhomboidal calcareous ſpar; unequiangular, as in topaz.—*Angles of the terminal edges*: theſe are either

either rectangular, as in cubic fluor; or oblique angular, which is either parallel oblique, as in the tetrahedral prism of feldspar, or alternate oblique, as in spinel, blende, and copper pyrites.—*Angles of the summit*: these are confined to the pyramid, and present the following varieties: they are called extremely acute, when the angle is from 10° to 30°, as in calcareous spar; very acute, from 30° to 50°, as in sapphire; acute, from 50° to 70°, as in calcareous spar; rather acute, from 70° to 90°, as in quartz; rectangular, as in zircon; rather obtuse, from 90° to 100°, as in honey-stone; obtuse, from 100° to 130°, as in calcareous spar; very obtuse, from 130° to 150°, as in tourmaline; extremely obtuse, from 150° to 170°.

ε. *The Direction of the Planes.*—They are either rectilinear or curvilinear: the former are the most common; the latter are distinguished according to the position of the curvature, which is either concave, as in fluor spar; convex, as in diamond; concave-convex, as in sparry iron-stone: or according to the form, which is either spherical, as in brown spar; cylindrical, in which the convexity is either parallel with the sides, as in iron pyrites, or parallel to the diagonal, as in fluor spar; and conical, as in gypsum.

ζ. *The Fulness of the Crystal.*—Crystals are either full and perfect, which is most commonly the case; or hollowed at the extremities, as in green lead ore; or entirely hollow, as the three-sided pyramidal calcareous spar from Schemnitz.

d. Modifications of the fundamental Form.—The changes or alterations which take place on the fundamental form are three; truncation, bevelment, and acumination.

α. *Truncation.*—This name is given to the plane which replaces an edge or a solid angle of a fundamental form. In the truncation are to be observed the parts of the truncation, *viz.* its planes, edges, and angles; and the determination of the truncation, which relates to its situation as it occurs at the edges or angles; its magnitude; its application, as being either straight, (equally inclined on the adjacent planes,) or oblique; its direction, which presents either an even or a curvated surface.

β. *Bevelment*—takes place when the edges, terminal planes, or angles, are replaced each by two smaller converging planes terminating in an edge. In this we have to consider the parts and the determination of the bevelment.—The parts of the bevelment: these are the planes, the angles, and the edges; of which latter there are two kinds, *viz* the proper edge, formed by the meeting of the two bevelling planes, and the edges formed by the bevelling and the adjoining planes:—the determination of the bevelment, in which is to be considered its situation, as it takes place either at the terminal planes, or at the terminal edges, or at the angles:—its magnitude, which is said to be slight or deep; the angle under which the bevelling planes meet; the continuation of the bevelment, which is either uninterrupted or interrupted, and this latter either once interrupted, as in the double three-sided pyramid of calcareous spar, or twice interrupted, as in barytes; and lastly, the application of the bevelment, which is said to be straight, when the edge formed by the meeting of the two planes is perpendicular to the axis, and oblique, when the edge is not perpendicular to the axis of the crystal.

γ. *Acumination.*—The fundamental figure is said to be acuminated when its angles or terminal planes are replaced at least by three planes, which converge into a point, and sometimes into an edge. In this we have, as in the preceding, to attend to the parts of the acumination, and its determination, which latter relates to its situation; to the planes themselves, in which are to be observed their number, relative size, form, and application; to the angle of the summit of the acumination, which is either obtuse and rectangular, or acute; to the magnitude of the acumination; and lastly, to its termination, which is either a point or a line.

ε. *Multiplied Modifications of the fundamental Figure.*—Besides the simple alterations or modifications of the fundamental figure, we often meet with multiplied or complicated alterations. These are said to be co-ordinate, when several different kinds of alteration occur together, as truncations and bevelments; and superimposed, when several of the same kind are placed on each other, as, for instance, when one acumination is surmounted by one or more. In describing these alterations, those ought to be mentioned first which are the largest and most essential.

C. *The Connection and Aggregation of the Crystals.*—According to this, crystals are either single or aggregated. The single crystals are either loose, or imbedded, or superimposed. The aggregated crystals are either regular or irregular. To the regular or determinate belong the twin crystals, as in staurolite, and the triple crystals, which latter, however, are very rare:—many, singly aggregated, crystals are such as are either heaped upon one another, as in calcareous and fluor spars; or adhering laterally, as in amethyst crystals; or lastly, promiscuously aggregated, as in grey antimony:—many, doubly aggregated, crystals are distributed according to the form they assume, whence the following are enumerated by Werner, *viz.* scopiform or fascicular; when aggregated, acicular and capillary crystals diverge from a common centre, as in zeolite, &c.:—fasciform, manipular, or sheaflike; when a number of crystals diverge towards both ends, and are narrower in the middle, such as prehnite and radial zeolite:—columnar; elongated, equally thick prisms adhering laterally together, are of this description, as in columnar barytes:—pyramidal; many crystals parallel to one another, but of which those in the middle are the highest, and the others decline on all sides, thus giving to the aggregation a pyramidal shape, as is exemplified by calcareous spar and amethyst:—rose-like; composed of very thin tables, variously curved, and so connected together, as to resemble a full-blown rose, as is the case with the variety of calcareous spar, called rose spar, from Joachimsthal:—amygdaloid; formed by tables accumulated in such a manner as to have an amygdaloid form, as in barytes:—globular; as in iron pyrites:—in rows; an aggregation in which the axes of all the crystals lie in one direction, like a string of pearls, as it is seen in calcareous spar, vitreous silver.

D. *The Magnitude of Crystals*, with regard to which they are divided into seven varieties, *viz.* uncommonly large; two feet and upwards in length, as in rock crystal:—very large; from two feet to six inches in length, as in beryl, calcareous spar:—large; from six inches to two in length:—middle-sized; from two inches to half an inch:—small; from half an inch to $\frac{1}{8}$th of an inch:—very small; from $\frac{1}{8}$th of an inch in length, to such as may just be distinguished by the naked eye, as in hornsilver:—microscopic; whose form cannot be distinguished by the naked eye, as in native gold, galena.

According to the relative dimensions, when compared with others, crystals are distinguished into short and low, long and high, broad and narrow, thick and thin, needle like, capillary, spicular, and globular, or tessular.

4. *Extraneous external Forms, or Petrifactions*, which are divided into those of animals and those of vegetables. See PETRIFACTIONS.

ij. *The external Surface.*—This is the second particular generic character of solid minerals; the following are its varieties, *viz.* uneven; having irregular elevations and depressions, as in calcedony:—granular; when the elevations

are ſmall, round, and nearly equal, as in ſtalactitical brown hematite :—druſy ; having minute, prominent, equal cryſtals on the ſurface, as in quartz :—rough ; when the elevations are minute, and almoſt imperceptible, as in quartz :—ſmooth :—ſingly ſtreaked : cryſtals are ſtreaked longitudinally, as in topaz, ſhorl ; tranſverſely, as in rock-cryſtal ; diagonally, as in aplome ; alternately ſtreaked, when the tranſverſe and longitudinal ſtreaks occur on alternate planes, cubic iron pyrite and brown iron-ſtone :—doubly ſtreaked ; plumiformly doubly ſtreaked, or like a feather, in native ſilver ; reticularly or net-ſhaped, as in grey cobalt ore.

iij. *The external Luſtre.*—In this third particular generic character we have to diſtinguiſh

a. The *intenſity* of the luſtre, of which there are five degrees, *viz.* ſplendent ; the ſtrongeſt kind of luſtre, as in galena and ſelenite :—ſhining ; as in barytes, pitch ſtone, copper pyrites :—gliſtening, or weakly ſhining, as in grey copper ore, porcelain, jaſper, and ſplintery quartz :—glimmering ; as in clay iron-ſtone, red hematite :—faintly glimmering, which may be exemplified by Lydian ſtone.

b. The *kind* of luſtre, which is either common or metallic. The common luſtre belongs chiefly to earthy ſtones and ſalts : it is vitreous or glaſſy ; as in rock cryſtal, topaz : —reſinous ; in pitch-ſtone, yellow lead ore :—pearly ; in cyanite, zeolite, and ſelenite :—adamantine ; in diamond, white lead ore :—ſemi-metallic ; in mica, red hematite. The metallic luſtre we have in copper pyrites, grey copper ore, &c.

II. *Aſpect of the Fracture.*—Here, as in the external aſpect, three kinds of characters preſent themſelves, *viz* the luſtre of the fracture, the fracture, and the form of the fragment.

1. The *luſtre* of the fracture, or the internal luſtre : its determination is the ſame as that of the external luſtre.

2. The *Fracture.* (*a.*) The *compact* fracture ; its varieties are ſplintery, either coarſe or fine ſplintery ; both of which kinds of fracture occur in horn-ſtone, lime-ſtone, and quartz : —even, as in galena, Lydian ſtone, calcedony, chryſopraſe : —conchoïdal ; which is diſtinguiſhed, according to the ſize, into large and ſmall ; according to the appearance, into deep and imperfect ; and according to the depth, into flat and conchoidal :—uneven ; which is either coarſe-grained, as in copper pyrites ; or ſmall-grained, as in copper niekel ; or fine-grained, as in arſenical pyrites :—earthy ; as in chalk, clay iron-ſtone, &c. :—hackly ; in which the fracture exhibits ſharp points, which is peculiar to the metals, as in native gold and native copper.

b. The *fibrous* fracture, in which are to be obſerved the thickneſs of the fibres, as they are coarſe, fine, or delicate ; gypſum, fine fibrous malachite, wood tin :—the direction of the fibres ; which is ſtraight, as in red hematite ; or curved, as in black hematite and fibrous rock-ſalt :—the poſition of the fibres, which is promiſcuous, as in plumoſe antimony ; parallel, as in amianth ; or diverging, which latter is diſtinguiſhed into ſtellular, as in brown hematite ; and ſcopiform, as in red hematite and malachite.

c. The *radiated* fracture, which is ſubdivided, according to the breadth of the rays, into uncommonly broad radiated, as in grey antimony ; broad radiated, as in actinote ; and narrow radiated. According to the direction of the rays ; into ſtraight radiated, and curved radiated. According to the poſition of the rays, into promiſcuous radiated, as in grey antimony ; parallel, as in hornblende ; and diverging, which latter is either ſtellular, as in cobalt bloom ; or ſcopiform, as in grey antimony. With regard to the aſpect of the rays, we find their ſurface either ſtreaked, as in hornblende, or ſmooth, as in actinote and antimony.

d. The *foliated* fracture, in which are to be determined the ſize of the folia :—the degree of perfection of the folia, according to which the fracture is ſpecular, as in galena ; perfectly foliated ; imperfectly foliated, as in fluor ſpar ; ſlaty, as in clay ſlate ; and concealed foliated, as in rock cryſtal : —the direction of the folia, which is ſtraight, as in ſelenite, or curved foliated ; this latter is ſubdivided into ſpherically curved, as in brown ſpar ; undularly curved, as in talc ; petaloïdally curved, as in a variety of feldſpar ; and indeterminately curved, as in mica :—the poſition of the folia ; it is either common foliated, in which the folia cover each other completely, or ſcaly, in which they cover each other partially, as in mica :—the aſpect of the ſurface of the folia, which is either ſmooth or ſtreaked.

e. The *Paſſage* or *Cleavage of the Folia*, which is diſtinguiſhed according to the number of the cleavages into ſingle, as in mica ; double, as in feldſpar, hornblende ; threefold, as in calcareous ſpar ; quadruple, as in fluor ſpar ; and ſextuple cleavage, as in blende :—according to the angle under which the cleavages interſect one another :—according to the greater or leſs degree of perfection of each cleavage.

Sometimes ſeveral kinds of fracture occur in one and the ſame mineral, ſo that one is contained in the other, in which caſe the fracture in the large is to be diſtinguiſhed from the fracture in the ſmall ; thus, for inſtance, the fracture of clay-ſlate may be flaty in the large, and earthy or uneven in the ſmall : or one fracture may traverſe the other, in which caſe the longitudinal or principal fracture is to be diſtinguiſhed from the tranſverſal or croſs fracture ; thus in baſaltic hornblende, the longitudinal fracture is ſtraight foliated, while the croſs fracture is ſmall conchoidal paſſing into uneven, &c.

3. *The Form of the Fragments*, which is either regular or irregular ; the *regular* are cubic fragments, as in galena, rock-ſalt :—rhomboidal, in which caſe the fragments are ſpecular on all planes, as in calcareous ſpar ; or ſpecular on four ſides, as in feldſpar ; or ſpecular on two ſides, as in ſelenite : —trapezoidal, as in foliated coal :—trihedral-pyramidal, as in fluor ſpar :—dodecahedral, as in blende. The *irregular* fragments are cuneiform, as in wood tin, red hematite :— ſplintery, as in aſbeſt, actinote :—tabular, as in mica, indurated talc :—indeterminately angular, which are moſt common, and are diſtinguiſhed, according to the degree of ſharpneſs which the edges of the fragments poſſeſs, into very ſharp-edged, as obſidian ; ſharp-edged, as horn-ſtone ; rather blunt-edged, as lime-ſtone ; blunt-edged, as gypſum ; and very blunt-edged.

III. *Aſpect of the diſtinct Concretions.*—Diſtinct concretions are thoſe maſſes into which certain minerals are naturally divided, and which can be ſeparated from one another without breaking through the ſolid or freſh part of the mineral. We conſider in them

1. The *form* of the diſtinct concretions ; it is granular, lamellar, and columnar.

a. The *granular* is diſtinguiſhed, with reſpect to form, into round granular, which again is ſpherically granular, as in roe-ſtone ; and lenticularly granular, as in red granular clay iron-ſtone :—angular-granular, which is either common, as in galena ; or elongated, as in zeolite. With reſpect to magnitude, the granular diſtinct concretions are large granular ; the ſize of hazel-nuts and upwards, as in galena, zeolite :—coarſe-granular ; from the ſize of a hazel-nut to that of a pea, as in blende, mica, pea-ſtone :—ſmall granular ; from the ſize of a pea to that of a millet-ſeed, as in galena, black blende :—fine granular ; from the ſize of a millet-ſeed to juſt diſcoverable by the naked eye ; roe-ſtone, ſparry iron-ſtone.

b. ***Lamellar***, which, with reſpect to direction, is ſtraight

lamellar; and again either quite ſtraight, as in ſome varieties of galena and barytes, or fortification-like, as in amethyſt: —curved lamellar, which is either indeterminate, as in ſpecular iron; reniform, as in native arſenic; ſpherical-concentric, as in calcedony, and conical-concentric, as in calcareous ſpar. With regard to thickneſs, into very thick lamellar, if above $\frac{1}{2}$ an inch in thickneſs, as in amethyſt: —thick lamellar, between $\frac{1}{2}$ and $\frac{1}{4}$ of an inch thick, as in amethyſt, barytes, galena:—thin lamellar, between $\frac{1}{4}$ and $\frac{1}{12}$ of an inch, as in barytes:—very thin lamellar, varying between a line and the thickneſs juſt perceptible by the naked eye, as in native arſenic and brown ſpar.

c. Columnar denominate thoſe diſtinct concretions in which the breadth and thickneſs are inconſiderable in compariſon of the length; theſe, with reſpect to direction, are ſtraight columnar, as in calcareous ſpar; and curved columnar, as in clay iron-ſtone. With regard to thickneſs, they are very thick columnar, as in quartz and calcareous ſpar; thick columnar, as in calcareous ſpar and amethyſt; thin columnar, as in clay iron-ſtone; very thin columnar, as in amethyſt, ſhorl. With reſpect to ſhape they are perfect columnar, when throughout of the ſame thickneſs; imperfect columnar, as in amethyſt and ſpecular iron; cuneiform columnar, as in calcareous ſpar and quartz. With reſpect to poſition, they are parallel columnar, as in quartz, and ſhorl beryl; diverging columnar, as in calcareous ſpar and clay iron-ſtone; and promiſcuous columnar, as in calcareous ſpar and arſenical pyrites. In ſeveral minerals two of theſe varieties, or different ſizes of the ſame variety of diſtinct concretions, occur together, either the one including the other, or the one traverſing the other.

2. *The Surface of the diſtinct Concretions.*—This is ſmooth, as in hematite; rough, as in clay iron-ſtone; ſtreaked, which is either longitudinally ſtreaked, as in ſhorl, obliquely, as in calcareous ſpar, or tranſverſely, as in amethyſt; uneven, as in brown blende.

3. *The Luſtre of the diſtinct Concretions*, which is determined in the ſame manner as the external luſtre.

IV. *The general Aſpect.*—This comprehends the tranſparency, the ſtreak, and the ſoiling.

1. The *Tranſparency*, which is diſtinguiſhed into tranſparent; which is again either ſimply tranſparent, or doubly tranſparent, as in calcareous ſpar (ſee REFRACTION, *Double*); ſemi-tranſparent, as in opal and calcedony; tranſlucent, as in pitch-ſtone, granular lime-ſtone; tranſlucent at the edges, as in horn-ſtone, heliotrope; opaque, as in chalk, &c.

2. The *Streak*, which is either of the ſame colour, as in chalk, or more or leſs different: thus crimſon red cinnabar yields a ſcarlet-red ſtreak; aurora red orpiment, an orange-yellow ſtreak. Moſt native metals have their luſtre increaſed by the ſtreak.

3. The *Soiling* minerals are diſtinguiſhed into ſuch as ſimply ſoil, and this either ſtrongly, as red ſcaly iron-ore; or ſlightly, as molybdena: and into ſuch as both ſoil and mark or write, ſuch as graphite, drawing-ſlate, and chalk.

V. *Characters for the Touch.*—To theſe Werner refers the hardneſs, the tenacity, the frangibility, the flexibility, and the adheſion to the tongue.

1. *The Hardneſs.*—This character is diſtinguiſhed into extremely hard, when the file makes no impreſſion on a mineral, ſuch as the diamond, ſapphire; very hard, when it makes a weak impreſſion, as on topaz and rock cryſtal: hard, when the file makes a conſiderable impreſſion, as on feldſpar; ſemi-hard, when it may be ſcraped with a knife, but gives no fire with ſteel, as baſalt, lime-ſtone: ſoft, when it is eaſily cut by the knife, and even yields to the nail of the finger, as gypſum and ſulphur.

2. The *Tenacity.*—Its degrees are; brittle, when the particles are in the higheſt degree coherent and immoveable, as in quartz, grey copper ore; ſectile, when the particles are coherent, but not perfectly immoveable among one another, as in galena; malleable or ductile, when the integrant particles are coherent, and alſo more or leſs moveable among one another, as in moſt of the native metals.

3. The *Frangibility.*—Its degrees are the following; very difficultly frangible, ſuch as moſt native metals; difficultly frangible, as baſalt; rather eaſily frangible, as flint, quartz; eaſily frangible, as opal; very eaſily frangible, as amber, &c.

4. The *Flexibility*, which is diſtinguiſhed into common, as in malleable minerals, amianth, &c.; and elaſtic, as in mica.

5. The *Adheſion to the Tongue*, according to which minerals poſſeſs this property ſtrongly, as hydrophane opal; rather ſtrongly, as bole; weakly, as talc; very weakly, as clay.

VI. *Characters for the Hearing.*—The *Sound.* It is ringing or ſounding, as in native arſenic; creaking, as in native amalgam when preſſed with the finger; grating or ruſtling, as in paſſing the finger over mountain cork and mealy zeolite.

Particular generic Characters of Friable Minerals.—The characters included under this article are, the external form, the luſtre, the appearance of the particles, the ſtain, and the friability.

1. The *external Form.*—According to this, friable minerals are maſſive, as porcelain earth; diſſeminated as blue iron earth; thinly coating, as black copper ore; ſpurious, as ſcaly brown iron-ſtone, or brown iron froth; dendritic, as earthy and grey manganeſe ores. 2. The *luſtre*, which is determined as in ſolid minerals; but friable minerals occur only as glimmering or dull: the glimmering is either common glimmering, as in indurated cobalt ochre; metallic glimmering, as in brown iron froth; pearly glimmering, as in earthy talc; dull, as in earthy cobalt ochre, &c. 3. The *aſpect of the particles*, which are either duſt-like, as in porcelain earth; or ſcaly, as in talc earth, chlorite earth. 4. The *ſoiling*, or *ſtain*, which is either ſtrong, as in iron froth; or ſlight, as in black cobalt ochre. 5. The *friability*, with regard to which, the particles of friable minerals are either looſe, that is, when they have no perceptible coherence, as in blue iron earth; or cohering, as in cobalt cruſt.

Particular generic Characters of Fluid Minerals.—In theſe Werner conſiders, 1. The *luſtre*, which is either metallic, as in mercury; or reſinous, as in petroleum. 2. The *tranſparency*; tranſparent, as in naphtha; turbid, as in petroleum; opaque, as in mercury. 3. The *fluidity*; fluid, as in mercury; viſcid, as in mineral tar.

Remaining common generic external Characters.

1. The *Unctuoſity*, of which there are four degrees, *viz.* meagre, as is the caſe with moſt minerals; rather greaſy, as pipe clay; greaſy, as fuller's earth and ſteatite; very greaſy, as talc.

2. The *Coldneſs*, which includes three degrees, *viz.* cold, ſuch as baſalt, jaſper, porphyry; rather cold, as ſerpentine gypſum; ſlightly cold, as amber. By this character, cut and poliſhed ſtones may often be diſtinguiſhed, as alſo real gems, from thoſe which are artificial.

3. The *Weight.*—In order to determine with accuracy the ſpecific gravity of minerals, a hydroſtatic balance is made uſe of; but when this cannot be had recourſe to, a mineral is examined, by lifting it in the hand, and comparing its weight, thus eſtimated by the feeling, with its volume, by which means an approximation may be made to its ſpecific gravity. Five degrees of this mode of eſtimating the weight

of

of minerals have been aſſumed, *viz.* 1. Supernatant; ſuch minerals as ſwim in water, as naphtha, mountain cork. 2. Light, ſuch as have a ſpecific gravity between 1.000 and 2.000 (taking water at 1.000); amber, mineral pitch, pitcoal. 3. Rather heavy; ſuch as have a ſpecific gravity between 2.000 and 4.000, which is the caſe with moſt kinds of ſtones, as amianthus, rock-cryſtal, mica, &c. 4. Heavy; when the ſpecific gravity is from 4.000 to 6.000, as in moſt metallic ores, ſuch as grey copper ore, red hematite, &c. 5. Extremely heavy; when the ſpecific gravity exceeds 6.000, which includes the native metals, as native gold, native ſilver, native copper, and ſome others, as galena, tinſtone cryſtals, ſulphuretted biſmuth, and vitreous ſilver ore.

4. The *Smell.*—It is characteriſtic of only a ſmall number of minerals. It is obſerved either of itſelf, without addition, and is bituminous, as in mineral pitch; ſlightly ſulphureous, as in native ſulphur and grey antimonial ore; bitteriſh, as in ochre kept cloſe ſhut up for ſome time; clayey, as in yellow chalk:—or, it is obſerved, after breathing on a mineral, which ſhould be cold and breathed upon ſtrongly and quickly, when the ſmell perceived is clayey bitter, as in hornblende, and ſome ſienites:—or it is obſervable, after rubbing or ſtriking, when the ſmell emitted is reſinous, as in ſwine-ſtone after rubbing; ſulphureous, as in pyrites; garlic, as in arſenical pyrites and white cobalt ore; empyreumatic, as in quartz and pitcoal.

5. The *Taſte*, which is characteriſtic of one claſs of minerals only, *viz.* the ſalts; and it is ſweetiſh ſaline, as rock-ſalt; ſweetiſh adſtringent, as native alum; ſouriſh adſtringent, as native vitriol; bitter ſaline, as native Epſom ſalt; cooling ſaline, as native nitre; lixivious, as native alkali; urinous, as native ſal ammoniac.

ORYCTOGRAPHY, formed of ορυκτος, *foſſil*, and γραφω, *I deſcribe*, is that part of natural hiſtory in which foſſils are deſcribed. See ORYCTOGNOSY.

ORYCTOLOGY, of ορυκτος, *foſſil*, and λογος, *diſcourſe*, is that part of phyſic which treats of foſſils.

ORYGIA, in *Botany*, a name perverted from the barbarous Arabic one *Horudjrudi*, and applied by Forſkall, in his Fl. Ægypt-Arab. 103, to a ſuppoſed new genus, eſtabliſhed by him, upon two ſpecies of PORTULACA, or rather TALINUM. See thoſe articles. See alſo Willd. Sp. Pl. v. 2. 861.

ORYGMA, ορυγμα, among the Athenians, a name given to the pit, more uſually called *barathrum*; whence the public executioner received the appellation of ὁ επὶ τω ορυγματι.

ORYX, in *Zoology*, a ſpecies of *Antilope*. See PASAN.

ORYZA, in *Botany*, an ancient name, ορυζα of the Greeks, ſuppoſed by profeſſor Martyn to be, poſſibly, derived from ορυσσω, *to dig*. Whether this name may have originally been applied to various ſorts of grain, or pulſe, procured by means of *digging*, or *cultivation*, the ſhort account given by Dioſcorides, decidedly indicates his ορυζα to have been our rice. "*Oryza*," ſays he, 'is a kind of grain, which grows in marſhy and watery places. It is moderately nutritious, and of a binding quality." Linn. Gen. 177. Schreb. 237. Willd. Sp. Pl. v. 2. 247. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 317. Juſſ. 32. Tourn. t. 296. Lamarck Illuſtr. t. 264. Gærtn. t. 80.—Claſs and order, *Hexandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two minute, pointed, nearly equal valves, containing one flower. *Cor.* of two boat-ſhaped, concave, compreſſed valves, of equal length; the broadeſt with five angles, and a terminal awn; the inner one narroweſt. Nectary of two minute flat leaves, at one ſide of the germen, each leaf narrow at the baſe, abrupt at the ſummit, deciduous. *Stam.* Filaments ſix, capillary, the length of the corolla; anthers cloven at the baſe. *Piſt.* Germen ſuperior, turbinate, angular; ſtyles two, capillary, reflexed; ſtigmas club-ſhaped, feathery. *Peric.* none, except the corolla, which becomes firmly attached to the ſeed, of an oval-oblong form, compreſſed, with thin edges, and two furrows at each ſide. *Seed* ſolitary, large, oblong, obtuſe, compreſſed, with two furrows at each ſide.

Eſſ. Ch. Calyx a glume of two valves, containing a ſingle flower. Corolla of two valves, angular, of equal length, growing to the ſeed.

1. O. *ſativa*. Common Rice. Linn. Sp. Pl. 475. Miller Illuſtr. t. 19. (Oryza; Camer. Epit. 192. Matth. Valgr. v. 1. 365. Ger. em. 79.)—Native of Ethiopia. Cultivated in tropical countries very abundantly, as well as in ſome of the warmer parts of Europe, in grounds for the moſt part artificially inundated. Gerarde had rice in his garden before 1596. It is annual, flowering in the middle of ſummer, and can only be kept in the ſtove. *Root* fibrous. *Herb* graſſy, about four or five feet high, light green, ſmooth. *Leaves* linear, narrow, taper-pointed. *Stipula* long, abrupt, jagged, crowning the very long ſtriated *ſheath*. *Panicle* terminal, much branched, many-flowered, nearly erect, ſlightly ſpreading; its branches angular, rough. *Flowers*, when cloſed, obovate, oblique, or moſt gibbous at one ſide; their *corolla* ſomewhat hairy, curiouſly and minutely granulated or dotted. *Awn* ſtraight, rough, various in length.

Moſt authors have conſidered this as the only ſpecies of *Oryza*. Loureiro ſays there are ſeveral varieties of it, and as he thinks ſome really diſtinct ſpecies, of which he gives the following particulars, to lead the way to fuller botanical obſervations.

1. O. *communiſſima*. Common Rice. Loureir. Cochinch. 215.—Of this the *ſtem* is four feet high. *Panicle* ſpiked, the ſpikes moſtly ſimple. Huſk of the *ſeed* pale, oblong, with long *awns*. This is a late ſort, gathered from ſix to eight months after it is ſown. It inhabits marſhy places; growing ſickly from drought, or a ſlight influx of ſalt water; and if expoſed in a great degree to either, it periſhes.

2. O. *præcox*. Early Rice. Ibid.—*Stem* three feet high. Panicle ſpiked, the ſpikes branched. Huſk of the *ſeed* turgid, browniſh-red; with ſhorter *awns*.—Ripens in the fourth month. Grows in marſhy places, but is not injured by ſalt inundations.

3. O *montana*. Mountain Rice. Ibid.—*Stem* as high as the laſt, but more ſlender. Huſk of the *ſeed* longer; the *awns* extremely long. It is ſown in dry mountainous ſituations. If expoſed to a continued inundation, it decays. Sea water kills it.

Sir Joſeph Banks has lately obtained ſeed of this valuable kind of rice, from the mountainous parts of India, where it is expoſed to a conſiderable degree of cold. It may prove a valuable acquiſition, if capable of culture in Europe.

4. O. *glutinoſa*. Glutinous Rice. Ibid.—*Stem* four feet high. *Leaves* broader, and yellowiſh. *Panicle* large, with ſhorter *awns*. *Seed* oblong, rather large, glutinous, uſually very white.—Grows both in watery and dry places. There is a variety whoſe *ſeed* is extremely black, and of an excellent flavour; as well as another with red *ſeed*. *Loureiro*.

This fourth ſort appears to be what J. Miller has figured, as above quoted.

Rice ſeems to contain more ſiliceous earth in its compoſition, than moſt of its natural order.—Even the ſeed is not deſtitute of this ſubſtance. Very brilliant imitations of

precious

precious ſtones are reported to be made of rice, for which purpoſe a prodigious quantity of the grain is required.—It is however a vulgar error that certain figures, cups, &c. of a whitiſh ſemitranſparent hue, brought from the Eaſt, and actually carved out of ſoap-rock, or ſome ſuch ſtone, are made of boiled rice.

ORYZA, in *Gardening*, contains plants of the exotic annual kind, of which the ſpecies is rice (O. ſativa).

There are ſeveral varieties of it, namely,

The *Common Rice*, which has the culm four feet high; the panicle ſpiked, the ſpikes commonly ſimple; the fruit oblong, pale, with long awns. It is late, and is cut from ſix to eight months after planting.

The *Early Rice* has the culm three feet high; the panicle ſpiked; ſpikes branching; the fruit turgid, browniſh-red, with ſhorter awns. It ripens and is cut in the fourth month from planting.

The *Dry*, or *Mountain Rice*, has the culm three feet high, and more ſlender; the fruit longiſh, with awns the longeſt of all. It is ſown on mountains, and in dry ſoils.

The *Clammy Rice* has the culm four feet high; the leaves wider, yellowiſh; panicle large, with ſhorter awns; the ſeed oblong, largiſh, glutinous, uſually very white. This is cultivated both in wet and dry places.

It varies with a black ſeed, which is higher flavoured, and alſo with a red ſeed.

And there are ſome other varieties.

Method of Culture.—Theſe plants may be increaſed by ſeeds in the early ſpring. They ſhould be ſown on a hot-bed, and when the plants are come up, be tranſplanted into pots filled with rich light earth, and placed in pans of water, which ſhould be plunged into a hot-bed; and as the water waſtes, it muſt be renewed from time to time. They muſt be kept in the ſtove all the ſummer, and towards the end of Auguſt they will produce the grain, which will ripen tolerably well, provided the autumn prove favourable for the plants.

They afford variety in the hot-houſe collections.

ORYZEUM, a name given by many of the chemical writers to gold.

ORYZOPSIS, in *Botany*, from ορυζα, *rice*, and οψις, *aſpect* or *reſemblance*, becauſe the plant has the habit of rice; a faulty appellation given by Michaux, contrary to the law which prohibits ſuch compounds or comparative generic names. Michaux Boreal-Amer. v. 1. 51. Vahl. Enum. v. 2. 397.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume ſingle-flowered, of two nearly equal, broadly elliptical, ſomewhat keeled, concave, ribbed valves, the outer one broader, and rather ſhorter. *Cor.* encompaſſed at the baſe with an annular tuft of hairs; its outer valve cloſe, coriaceous, oval, ſomewhat cylindrical, ſmooth, with a terminal ſetaceous awn; inner concealed by the outer, much narrower, nearly linear, awnleſs. Nectary of two linear leaflets, the length of the germen. *Stam.* Filaments three; anthers rather prominent, long, linear, rather bearded at the point, ſlightly cloven at the baſe. *Piſt.* Germen ſuperior, oblong; ſtyle a little longer than the corolla, ſlender, compreſſed, minutely downy at the edge; ſtigmas two, ſpreading, capillary, minutely glandular, and downy. *Seed* ſolitary.

Eſſ. Ch. Calyx of two valves, ſingle-flowered. Corolla of two valves; the outermoſt awned. Nectary of two linear leaves.

1. O. *aſperifolia*. Michaux t. 9.—Native of the chain of mountains from Hudſon's Bay to Quebec. *Stems* ſeveral, unbranched, with one or two knots; leafy at the bottom. Loweſt *leaf* almoſt as long as the ſtem, linear-lanceolate, acute; upper ones remote, ſhort, narrow, flattiſh, rigid, rough-edged, and rather pungent, much ſhorter than their ſheaths. *Flowers* in a racemoſe panicle, not numerous, reſembling thoſe of rice in general aſpect, but totally unlike in ſtructure, the *calyx* being moſt like the *corolla* of *Oryza*. Vahl, after Richard, deſcribes the *ſtyle* as three-cleft, though the *ſtigmas* are ſaid to be but two.

ORZERO, in *Geography*, a town of Iſtria, in the gulf of Venice, near the ſea; 5 miles N. of Rovigno. N. lat. 45° 13′. E. long. 13° 53′.

Os, or *Oſs*, in *Geography*, a town of Brabant; 10 miles N.E. of Bois-le-Duc.

OSA, a river of Etruria, which runs into the ſea, N. lat. 42° 38′. E. long. 11° 12′.—Alſo, a town of Ruſſia, in the government of Perm, on the Kama; 80 miles S.W. of Perm. N. lat. 56° 56′. E long. 53° 54′.

OSA *de la Vega*, *La*, a town of Spain, in New Caſtile; 36 miles S. of Huete.

OSACEA, a ſea-port town of Japan, in the iſland of Niphon,

Niphon, and, next to the two capitals Meaco and Jedo, the moſt conſiderable for wealth, munificence, and population. It is ſituated in a large bay, to which it gives name, near the mouth of the river Jedogawa, which is ſaid to be here as large as the Thames at London. The port is defended by a ſtrong caſtle, commanding the city and river, and always well garriſoned. Oſacea abounds with all ſorts of proviſions and merchandiſe. The neighbouring country furniſhes an heath of a beautiful orange-colour, with which they cover their houſes, and great quantities of which they convey to other parts of the empire for the ſame purpoſe; 25 miles S.W. of Meaco. N. lat 35° 8′.

OSADA, a ſmall iſland in the Sooloo Archipelago. N. lat. 6° 5′. E. long. 120° 28′.

OSAGE, a river of Louiſiana, which runs from the W. into the right bank of the Miſſouri; about 24 miles from the Miſſiſippi.

Osages, an Indian nation which inhabits the vicinity of the above-named river, on the right bank of the Miſſouri, about 80 leagues from its confluence with it. This nation numbers 2000 warriors, who occupy two ſettlements near each other. Their ſtature is gigantic and well-proportioned: they are enemies of the whites, and of all other Indian nations, and commit depredations from the Illinois to the Arkanſas. The trade of this nation is ſaid to be under an excluſive grant. The people are a cruel and ferocious race, hated and dreaded by all the other Indians.

OSARA, a town of Japan, in the iſland of Niphon. N. lat. 35° 10′. E. long. 136° 40′.

Osara, *Aſchara*, or *Aſara*, a town of Syria, in the Deſert, near the Euphrates; 170 miles E.S.E. of Aleppo.

OSBANIKET, a town of Turkeſtan, on the Sirr; 30 miles W. of Toucat.

OSBECKIA, in *Botany*, received its name from Linnæus, in honour of his diſciple Peter Oſbeck, a Swediſh clergyman, who performed a voyage to China, as chaplain to a Swediſh Eaſt Indiaman, and publiſhed an account of his voyage, particularly of his obſervations in natural hiſtory, which has been tranſlated into German and Engliſh. The author was living, a few years ſince, at an advanced age, as a country clergyman in Sweden, nor have we heard of his death. He has contributed ſeveral papers on fiſhes, inſects, and various economical plants, to the Stockholm Tranſactions. Linn. Gen. 186. Schreb. 249. Willd. Sp. Pl. v. 2. 300. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 340. Juſſ. 330. Lamarck Illuſtr. t. 283. Gærtn. t. 126?—Claſs and order, *Octandria* (or rather perhaps *Decandria*) *Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Melaſtomæ*, Juſſ.

Gen. Ch. *Cal.* perianth of one leaf, bell-ſhaped, permanent; limb in four or five deep, oblong, acute ſegments, with intermediate fringed ſcales. *Cor.* Petals four or five, roundiſh, ſeſſile, longer than the calyx. *Stam.* Filaments eight or ten, thread-ſhaped, ſhort; anthers oblong, erect, or ſlightly curved, each terminated by a ſlender beak about its own length. *Piſt.* Germen ovate, cloſely united with the body of the calyx in the lower part, terminating above in four or five fringed ſcales; ſtyle cylindrical, ſlightly curved, the length of the ſtamens; ſtigma ſimple, obtuſe. *Peric.* Capſule roundiſh-ovate, firmly clothed with the body of the calyx, (which is tubular and abrupt at the ſummit), of four or five cells, burſting longitudinally at the top. *Seeds* numerous, kidney-ſhaped. *Receptacles* lunate.

Eſſ. Ch. Calyx with four or five deciduous teeth, and fringed intermediate ſcales. Petals four or five. Anthers beaked. Capſule of four or five cells, clothed with the abrupt body of the calyx.

Obſ. There is ſome difficulty in diſtinguiſhing this genus from *Rhexia*. Willdenow juſtly remarks that "the capſule of the latter is encloſed in the calyx;" but it can ſcarcely be ſaid that "the germen is inferior in *Oſbeckia*." It is indeed cloſely united with the calyx, which in ſome new African ſpecies is clothed with curiouſly fringed ſcales, though naked in the original Chineſe one. In *Rhexia* the body of the calyx is not connected with the capſule. Perhaps, however, the permanent and ſimple teeth of the calyx, deſtitute of intermediate ſcales, may prove the beſt character of *Rhexia*. The dry capſular fruit diſtinguiſhes *Oſbeckia* from *Melaſtoma*, to ſay nothing of the calyx. Linnæus in his *Prælect. in Ord. Nat. Plantarum*, 335, ſeems to think *Rhexia* ſcarcely well diſtinguiſhed from *Oſbeckia*, not adverting to the connection of the calyx, nor to its teeth.

* *Flowers four-cleft, with eight ſtamens.*

1. O. *chinenſis*. Chineſe Oſbeckia. Linn. Sp. Pl. 490. Oſb. Voy. Engliſh edition; 342. t. 2. Lamarck t. 283. f. *a*, *b*, *c*.—Body of the calyx naked; ſcales ſquare, tipped with radiating briſtles. Leaves linear-lanceolate, nearly ſeſſile.—Gathered by Oſbeck, on hills not far from Canton, flowering in September. The Chineſe call it by a name which is equivalent to *Plume of Golden Roſes*. It is ſold in their apothecaries' ſhops, being taken in infuſion for the colic, and uſed in fomentations for ſprains and ſwellings. The *root* is woody, perennial. *Stems* ſeveral, branched or buſhy, not above eighteen inches high, ſlender, ſquare, leafy, rough, with minute cloſe-preſſed briſtles. *Leaves* oppoſite, on very ſhort ſtalks, linear-lanceolate, acute, entire, rounded at the baſe, an inch or more in length, three-ribbed, rough, with depreſſed briſtles, as in *Melaſtoma*; dark green above; pale or yelliowiſh beneath. *Flowers* terminal, uſually two together, ſeſſile, accompanied by ovate fringed *bracteas*. *Calyx* ovate, obſcurely ribbed, colored, perfectly ſmooth and naked; teeth four, about as long as the body, lanceolate or oblong, at firſt erect, folding over each other in the form of a cone bearded at the ſummit, then ſpreading, and finally deciduous, their edges fringed with pale hairs; intermediate ſcales external with reſpect to the teeth, ſmall, quadrangular, each crowned with a radiating tuft of unequal, pale, ſomewhat compound briſtles, half the length of the teeth, all finally deciduous. *Petals* red, obovate, broad, nearly twice as long as the calyx. *Anthers* yellow, with a pale wavy beak. After all the other parts of the *flower* are fallen, the *germen* remains crowned with a little ſtalked tuft of ſhort radiating briſtles, which perhaps are the fringed ſcales mentioned in the generic deſcription of that part.

2. O. *zeylanica*. Ceylon Oſbeckia. Linn. Suppl. 215. Willd. n. 2. Ait. n. 1. Lamarck f. *d*. (Echinophora maderaſpatana, ſideritidis non ſerratis nervoſis foliis, fructu capſulari caucalidis æmulo; Pluk. Phyt t. 173. f. 4.)—Briſtles of the calyx palmate, three-cleft, deflexed; ſcales linear, tipped with radiating briſtles. Leaves elliptic-lanceolate, ſtalked.—Native of Ceylon, from whence it was procured by ſir Joſeph Banks, in 1799, for Kew garden; it flowers about July in the ſtove, and is biennial. *Root* of a few ſmall zigzag fibres. *Stem* ſolitary, a ſpan high, ſlightly branched, ſquare, with briſtly angles. *Footſtalks* about a quarter of an inch long, briſtly. *Leaves* thinner, broader, more elliptical, and paler than in the firſt ſpecies, not well repreſented in the above figures. *Flowers* from one to five at the tops of the ſtem or branches, the lower ones on ſhort ſmooth axillary *ſtalks*. Body of the *calyx* pale, with eight ſtrong ribs, along which are ranged ſeveral minute ſcales, each bearing three widely ſpreading ſlender briſtles; teeth four, oblong, ſingle-ribbed, elegantly pectinate

tinate at the edge, not ſo ſoon deciduous as in the former; ſcales linear, narrow, crowned with a radiant orbicular tuft of ſimple briſtles.

Gærtner's figure, marked *O. hirta*, which he thought might belong to this or the foregoing, has certainly nothing to do with either, the *calyx* being five-cleft, without intermediate ſcales, and its briſtles ſcattered and ſhort.

We have a ſpecimen, gathered at Sierra Leone by the celebrated Dr. A. Afzelius, which agrees exactly with the original ones of *O. zeylanica*, except that the *flowers* are five-cleft and decandrous, as in all the following. We conſider it nevertheleſs as a mere variety.

** *Flowers five-cleft, with ten ſtamens.*

3. *O. antennina.* Briſtle-ſcaled Oſbeckia.—Body of the calyx naked; ſcales linear, longer than the teeth, fringed with diſtant briſtles. Leaves ovate, five-ribbed—Gathered by Dr. Afzelius, at Sierra Leone. *Stem* branched, ſpreading, ſquare, briſtly. *Leaves* ovate, about two inches long, light green, thin, very briſtly, with five ribs; their *ſtalks* about half an inch long, clothed with remarkably numerous, ſpreading, long, and ſtout briſtles. *Flowers* ſituated as in both the foregoing, but larger, and on longer ſtalks. Body of the *calyx* quite ſmooth and naked, very obſcurely ribbed, green, with a purpliſh tinge; teeth five, as long as the body, ovato-lanceolate, taper-pointed, pale green, tinged with purple, furniſhed with many fine ribs, the edges fringed with ſhort briſtles, the point tipped with a few long ones; ſcales rather longer than the teeth, linear, very narrow, purpliſh, fringed with long very diſtant briſtles, three of which crown the ſummit. The *petals* ſeem to be white or yellowiſh.

4. O. *rotundifolia.* Round-leaved Oſbeckia.—Briſtles of the calyx numerous, ſtellated; ſcales linear, tipped with radiating briſtles. Leaves roundiſh-ovate, three-ribbed.—From Sierra Leone.—The *branches* are reddiſh and hairy. *Leaves* about an inch long, remarkably broad, with only three ribs. *Footſtalks* half as long, very hairy. *Calyx*, in the only flower we have ſeen, almoſt globoſe, pale, purpliſh; its body clothed with copious, entangled, ſtellated briſtles; teeth five, linear-lanceolate, obtuſe, recurved, half the length of the body, copiouſly fringed and bearded; ſcales linear, very like the teeth, but much narrower, the terminal briſtles more radiating.

5. O. *tubuloſa.* Long-necked Oſbeckia.—Calyx minutely briſtly; its neck tubular, elongated; body clothed with ſtellated briſtles; ſcales linear, tipped with radiating ones. Leaves ovate, pointed, five-ribbed.—From Sierra Leone.—*Leaves* larger than in the laſt, of a broad-ovate, taper-pointed figure, with five ribs; both ſides hairy; the under much the paleſt. *Flowers* four or five, in a looſe terminal ſpike. *Calyx* ovate, with a cylindrical neck as long as the body, every part, even the teeth, denſely clothed with minute, ſcattered, pale, yellowiſh, depreſſed briſtles, beſides which the body is covered with large ſtar-like tufts of roughiſh, long, ſpreading briſtles, of the ſame hue. *Scales* linear, half as long as the five teeth, but much narrower, and tipped like them with radiating browniſh briſtles.

6. O. *grandiflora.* Large-flowered Oſbeckia.—Briſtles of the calyx tufted, unequal; ſcales linear, ſhort, tipped with radiating briſtles; teeth four times as long, obtuſe. Leaves ſeſſile, oblong. Panicle forked.—Native likewiſe of Sierra Leone. A much larger plant than any of the foregoing. *Stem* and *branches* hairy. *Leaves* nearly or quite ſeſſile, in diſtant pairs, elliptic-oblong, five-ribbed, hairy, bright green, ſomewhat recurved. *Flowers* about ſeven in a terminal, forked, hiſpid, leafleſs panicle, very large and handſome, purple, with yellow *anthers*. *Bracteas* ovate, obtuſe, fringed, deciduous. *Calyx* nearly cylindrical, its body deſtitute of minute depreſſed briſtles, but clothed with numerous, tranſverſe, oblong tufts, of long unequal ſpreading ones; teeth five, oblong, blunt, broad, nearly as long as the body, veiny, coloured, ſmooth, except a fine marginal fringe, and a thick tuft of unequal terminal briſtles; ſcales linear, a quarter the length of the teeth, ſmooth, crowned with an exactly ſimilar briſtly tuft. *Petals*, *ſtamens*, and *ſtyle*, about thrice as long as the calyx-teeth. This magnificent ſpecies would be a great acquiſition to our ſtoves. It appears to be herbaceous, but we have no account of its whole ſtature, or duration.

7. O. *multiflora.* Many-flowered Oſbeckia.—Briſtles of the calyx ſcattered, moſtly ſimple,; teeth linear, obtuſe. Leaves ovate, five-ribbed, ſtalked. Spikes aggregate.—This alſo was brought from Sierra Leone. It has the habit and infloreſcenee of a *Melaſtoma*. The *leaves* are ſtalked, two or three inches long, broad-ovate, pointed, rough with depreſſed briſtles, and furniſhed with five, ſometimes ſeven, ribs; their under ſide paleſt. *Spikes* terminal, about three together, each ſimple, racemoſe, of from three to ſix *flowers*, briſtly. We have ſcarcely ſeen the *flowers*, except one bud, in which the teeth of the *calyx* appear to be linear, ſmooth, with a radiating tuft of terminal briſtles; the intermediate ſcales we have not ſeen, but we obſerve the ſcars where they have been, on ſeveral advanced ſpecimens of the *calyx*, which is there ovate, with a ſhortiſh neck, and five marginal notches where the teeth and ſcales have ſtood. Its body is clothed with numerous, ſhort, ſcattered, upright or inflexed, yellowiſh briſtles, moſtly ſimple, but a few towards the top are gathered into palmate tufts. The *capſule* is firmly coated with the body of the calyx, but the tubular neck riſes altogether above it. This can hardly be Gærtner's *O. hirta*, though more reſembling it than any that has fallen in our way.

We truſt our learned friend Afzelius, to whom we are obliged for ſpecimens of the laſt five ſpecies, will pardon us for anticipating his publication of them; as our only deſign in doing ſo, after having kept them by us fifteen years, is to commemorate his diſcoveries, and to add freſh laurels to his diſtinguiſhed countryman's fame. Theſe new ſpecies confirm the genus and its characters, which have hitherto been ſo imperfectly known, that it has been in ſome danger of abolition. Juſſieu knew *Oſbeckia* merely from Linnæus, and Lamarck has adviſed its conjunction with *Melaſtoma*, the impropriety of which will ſufficiently appear from all we have ſaid. S.

OSBORN, Francis, in *Biography*, an ingenious Engliſh writer, ſon of ſir John Oſborn of Chickſand, Bedfordſhire, was born in 1589. In early life he frequented the court, and became a retainer of the Pembroke family, and finally maſter of the horſe to William earl of Pembroke. During the civil contentions of Charles I. he took part with the parliament, under which, and under Cromwell, he held ſome public employments. In the latter part of his life he reſided at Oxford, in order that he might ſuperintend the education of his ſon, and print ſome of his works. He died in February 1658—9. The work by which he is beſt known is his "Advice to a Son," of which the firſt part was printed in 1656, and the ſecond in 1659 It conſiſts of maxims and directions upon a variety of topics, highly important in the right conduct of life, delivered chiefly in the ſententious manner. From this work, the author of the article in the Biographia Britannica has made large extracts, which exhibit the talents of Mr. Oſborn in a ſtriking point of view. There is, however, a certain freedom in his expreſſions, and in many of his ſentiments, that ill-accorded with

with the taſte of the time, and he was charged with Atheiſm. The vice-chancellor of Oxford was urged to cauſe the book to be publicly burnt, which he refuſed; but an order was procured to prohibit the ſale of it, which, in fact, greatly increaſed its popularity. "This writer," ſays his biographer, "has been cited as giving an opinion in preference of a public education over a private one. In fact, he was ſenſible of what he had loſt by eſcaping the diſcipline of a public ſchool, but perhaps he did not ſo well compute the advantages that he had gained by the domeſtic plan of education; and theſe perſonal and individual conſequences ſeem to have influenced moſt of thoſe who have treated on the ſame ſubject." His other publications were various tracts upon political topics; *viz.* "Hiſtorical Memoirs on the Reigns of Queen Elizabeth and King James;" "A Miſcellany of ſundry Eſſays, Paradoxes, and problematical Diſcourſes, Letters, and Characters; together with Political Deductions from the Hiſtory of the Earl of Eſſex, executed under Queen Elizabeth" Biog. Brit.

OSBORNE, Peregrine, *Duke of Leeds*, was the third ſon of ſir Thomas Oſborne, bart., afterwards created baron Kiveton, viſcount Latimer, and earl of Danby, by king Charles II., and raiſed by king William to the dignities of marquis of Carmarthen and duke of Leeds. Peregrine, the ſubject of this article, was called up, by writ, to the houſe of peers, and took his ſeat in that aſſembly on the 19th of March 1689-90, by the title of lord Oſborne of Kiveton. He appears to have entered the naval ſervice of his country in early life, to have ſerved as volunteer on board divers ſhips, and was, on the 2d of January 1691, appointed commander of the Suffolk. He continued as a private captain till July 1693, having, in the intermediate time, greatly diſtinguiſhed himſelf at the battle off La Hogue. In the early part of the year 1693, he was appointed commander of the Royal William, a firſt rate of a hundred guns, and on the 12th of July, of the ſame year, was promoted to be rear-admiral of the red. In the following year he ſerved under lord Berkeley as rear-admiral of the blue, and requeſted the command of the detachment ordered to attack Breſt. This was thought to be one of the moſt deſperate undertakings ever allotted to any commander, and the ſteady reſolution which he manifeſted in carrying his orders into execution, reflects on him a greater honour than could have been acquired in a leſs arduous undertaking by the moſt brilliant victory. Having ſhifted his flag into the Monk, he led his detachment, and ſaw his ſhips poſted in the ſeveral ſtations aſſigned to them. The ſervice was attended with the greateſt danger; for they were not only very warmly received by a number of batteries of heavy cannon and mortars; but as ſoon as the Monk and the other ſhips had brought up, three heavy maſked batteries, of which the aſſailants were perfectly ignorant, ſuddenly opened upon them, and rendered their utmoſt exertions of no avail. The commander had on this occaſion a very narrow eſcape, a ſhell burſting in the ſhip, killing a marine who ſtood cloſe to him. After his return from this unfortunate expedition, he was appointed to command the fleet which convoyed the king from Holland. In 1697 he was appointed colonel of the firſt regiment of marines; it does not, however, appear that he had any ſubſequent command, but received the regular promotions, till he attained in 1708 the higheſt rank in the ſervice, *viz.* admiral and commander-in-chief of the fleet. In 1712 he ſucceeded his father as duke of Leeds, and died in June 1729, in the ſeventy-firſt year of his age. Sharnock's Biographia Novalis, vol. ii.

OSCARI, in *Geography*, a town of Sardinia; 23 miles S.E. of Caſtel Aragoneſe.

OSCASATO, a town of Italy, in the department of the Upper Po; 12 miles N.W. of Cremona.

OSCHA, a river of Ruſſia, which runs into the Irtiſch, oppoſite to Melanova, in the government of Tobolſk.

OSCHATZ, or Ozzek, a town of Saxony, in the margraviate of Meiſſen, containing three churches, a college, and ſome manufactures of cloth; 16 miles N.W. of Meiſſen. N. lat. 51° 18′. E. long. 13° 5′.

OSCHEOCELE, from οσχεον, *the ſcrotum*, and κηλη, *a ſwelling*, in *Surgery*, a ſcrotal hernia: See Hernia.

OSCHERSLEBEN, in *Geography*, a town of Weſtphalia, in the principality of Halberſtadt, on the Bode; 10 miles N.N.E. of Halberſtadt. N. lat. 50° 2′. E. long. 11° 28′.

OSCHETZKA, a town of Pruſſia, in the palatinate of Culm; 23 miles E. of Culm.

OSCHOPHORIA, in *Antiquity*, feaſts inſtituted by Theſeus, in acknowledgment for his having deſtroyed the Minotaur, and by that means freed his country, Athens, from the tribute of ſeven young men, who were to be ſent every year into Crete, to be devoured by that monſter. The word is formed from the Greek οσχη, *branch of a vine laden with grapes*, and φερω, *I bear*. Plutarch ſays, they were ſo named, becauſe inſtituted by Theſeus at his return to Athens, which happened to be at the time of vintage. Some ſay, the Oſchophoria were inſtituted in honour of Minerva and Bacchus, who had aſſiſted Theſeus in his enterpriſe. Others, that they were in honour of Bacchus and Ariadne.

To celebrate the Oſchophoria, the young people, who had fathers and mothers alive, ran to the temple of Bacchus and that of Minerva, with grapes in their hands. He, who arrived there firſt, was the conqueror, and was to perform the ſacrifice, by pouring out of a phial a mixture of wine, honey, cheeſe, flour, and oil.

OSCILLA, ſmall images of wax or clay, made in the ſhape of men or women; which were conſecrated to Saturn, in order to render him propitious.

OSCILLATION, in *Mechanics*, *vibration*; or the reciprocal aſcent and deſcent of a pendulum.

Oscillation, *Axis of*, is a right line, parallel to the apparent horizontal one, and paſſing through the centre; about which the pendulum oſcillates. See Pendulum.

M. Huygens's whole doctrine of oſcillation is founded on this hypotheſis, that the common centre of gravity of ſeveral bodies, connected together, muſt return preciſely to the ſame height whence it fell; whether thoſe weights return conjointly, or whether, after their fall, they return ſeparately; each with the velocity it had then acquired.

This ſuppoſition was oppoſed by ſeveral, and very much ſuſpected by others. And ſome, who inclined to believe it true, yet thought it too daring to be admitted into a ſcience which demonſtrates every thing.

At length M. James Bernouilli demonſtrated it by ſtrict geometry, by referring the weights to a lever; and publiſhed in the Mem. Acad. of Scien. of Paris for the year 1703. After his death, a more eaſy and natural demonſtration of the centre of oſcillation (ſee Center *of Oſcillation*,) was advanced by his brother, and publiſhed in the Mem. of the ſame Academy, for the year 1714: the ſubſtance whereof may be conceived as follows:

A ſimple pendulum of a determinate length and weight, raiſed to a determinate height, whence it is to fall till it recovers its vertical line, employs in that fall, or demi-vibration, a determinate ſpace of time, which can never poſſibly be either greater or leſs. Which time is neceſſarily ſuch, becauſe the agitative force, *i. e.* the force which produces

the motion of the pendulum, is determined in every thing that concurs to the formation thereof: ſo that it can only cauſe one certain effect.

The agitative force of the pendulum ariſes from three things: 1. The power or momentum of gravity. 2. The maſs or body tied to the end of the inflexible rod. 3. The diſtance of that body from the point of ſuſpenſion, or, which is the ſame, the length of the rod, or the pendulum.

Now, 1. The power of gravity, be the cauſe what it will, is that power, which makes a body fall, and that, *v. gr.* at the rate of $15\frac{1}{12}$ Paris feet in the firſt ſecond of time. It is viſible, then, that this force is the effect of a quantity, which determines thoſe $15\frac{1}{12}$ feet, and that a heavy body would paſs more or leſs ſpace in the ſame firſt ſecond, if the force of gravity were greater or leſs.

2. As that force is inherent in each point, or infinitely ſmall part of a body, the greater the body is, or the larger its maſs, the greater quantity of motion or force it has.

3. The diſtance of the moving body from the point of ſuſpenſion, or the length of the rod, is always the radius of a circle, of which the moving body deſcribes an arc; and of conſequence, the greater the radius is, *cæteris paribus*, the larger arc the body deſcribes. And, at the ſame time, the greater height it falls from, the greater velocity it acquires.

Now, the agitative force of the pendulum is only that of the body faſtened to the end of the rod. So that it is the product of the force of the weight of the maſs of that body, and of its diſtance from the point of ſuſpenſion. The force of gravity, therefore, being always the ſame, and a body or weight, faſtened to the end of the rod, always the ſame, it is impoſſible, that two ſimple pendulums, of a different length, ſhould be ſo iſochronal, or ſhould make their vibrations in the ſame time; for by virtue of thoſe different lengths, the velocities will be unequal, and of conſequence, the times of their vibrations will be ſo.

But if it be ſuppoſed, that there are, in nature, different powers of gravity, it will then be poſſible, that two ſimple pendulums, of different lengths, ſhould be iſochronal; the one animated by the natural weight, the other by the imaginary one.

If the imaginary gravity or weight be greater than the natural one, the pendulum, imagined iſochronal to the natural one, will neceſſarily deſcribe a larger ſpace or arc in the ſame time; and of conſequence the weight will be faſtened at a greater diſtance from the point of ſuſpenſion. Though, to have an iſochroniſm, the two agitative forces of the two pendulums muſt be equal; yet, of the three things which compoſe theſe forces, there are always two greater in the imaginary than the real pendulum: the third, therefore, *i. e.* the maſs or ball, muſt be diminiſhed in the neceſſary proportion.

As the ſpace or arc deſcribed by the imaginary pendulum is greater than that by the natural pendulum, in the ſame ratio as the imaginary gravity is greater than the natural one, and a radius of that arc greater in the ſame ratio, are two things inſeparable; the two gravities will be always to one another, as thoſe two radii, or the two lengths of the two pendulums; which always gives the expreſſion of the imaginary gravity, and, by a neceſſary conſequence, that of a diminiſhed maſs or ball of the imaginary pendulum. If the power of gravity be imagined leſs than that of the natural one, it is eaſy to obſerve how it is to be taken; but that were needleſs in our deſign.

If now there be a compound pendulum, charged with two weights or balls faſtened to the ſame rod, M. Bernouilli conceives each of thoſe weights removed to a greater diſtance from the point of ſuſpenſion than it was before; but both to the ſame; and diminiſhed, in maſs, in a due proportion: ſo as that both together only make one ſimple pendulum, animated with one weight, the expreſſion of which is had, and iſochronal to the natural compound pendulum.

Thus, we ſhall have one ſimple natural pendulum iſochronal to the compound natural one, by having a ſimple natural pendulum iſochronal to the ſimple imaginary pendulum before found; which is very eaſy: ſince, as the imaginary gravity is to the natural, ſo is the length of the ſimple imaginary pendulum to the length of the ſimple natural pendulum; and it is there the centre of oſcillation is required.

We ſhould here take notice that Mr. Taylor, a celebrated mathematician of our own country, diſcovered about the ſame time with Mr. John Bernouilli, a ſimilar ſolution of this problem, and publiſhed it in his "Methodus Incrementorum." See PENDULUM.

OSCILLATION, *Centre of.* See CENTER *of Oſcillation.*

OSCINES, among the Romans, an appellation given to ſuch birds, from whoſe chattering or notes, omens and predictions were drawn. See ALITES.

OSCITATION, the act popularly called *yawning.*

OSCULA, in *Anatomy*, a term uſed for the orifices, or openings of the larger veſſels.

OSCULATION, in *Geometry*, is uſed for the contact between any given curve and its oſculatory circle; that is, the circle of the ſame curvature with the given curve. See CURVATURE.

OSCULATORY, in *Church Hiſtory*, a tablet, or board, with the picture of Chriſt, or the bleſſed Virgin, or ſome other of the ſaints, which, after the conſecration of the elements in the euchariſt, the prieſt firſt kiſſed himſelf, and then delivered to the people for the ſame purpoſe.

OSCULATORY *Circle*, in *Geometry*, is uſed chiefly by foreign mathematicians, for the circle of curvature; that is, the circle having the ſame curvature with any curve at any given point. See CURVATURE.

OSCULATORY *Parabola.* See PARABOLA.

OSCULATORY *Point*, the point of contact between a curve and its oſculatory circle. See CURVATURE.

OSCULUM, in *Analytical Geometry.* See CURVATURE and EVOLUTE.

OSCULUM *Pacis.* Anciently it was a cuſtom in the church, that, in the celebration of maſs, after the prieſt had conſecrated the water, and ſpoken the words, *Pax Domini vobiſcum*, the people kiſſed each other; which was called *oſculum pacis.*

When this cuſtom was abrogated, another aroſe; and, while the prieſts ſpoke the words, a deacon, or ſubdeacon, offered the people an image to kiſs; which they called *pacem.*

OSEMANPOUR, in *Geography*, a town of Bengal; 20 miles E. of Burdwan. N. lat. 23° 11′. E. long. 88° 20′.

OSEN, a town of Norway, in the dioceſe of Drontheim; 56 miles N. of Drontheim.

OSENOKA, a river of Ruſſia, which runs into the Kolima, N. lat. 64° 15′. E. long. 148° 14′.

OSER, a river of Ruſſia, which runs into the Oka, 20 miles N.N.W. of Riazan.

OSERO, an iſland in the Adriatic, near the coaſt of Dalmatia, ſeparated by a narrow ſtrait from the S.W. end of the iſland of Cherſo; about 15 miles long, and from two to five broad. The air of this iſland is peſtilential in the heat of ſummer, which is owing to pools of brackiſh water, that ſtagnate for want of an outlet, and become putrid. Their city,

city, which is well ſituated in the iſland, and which was formerly populous, is nearly ruined, and become almoſt uninhabitable, by an exiſting evil, which, if the inhabitants had not been both indolent and poor, might have been eaſily removed. Several good benefices are annexed to the church of Oſero, which have been ſhamefully miſapplied, inſtead of being employed for the relief of the inhabitants, and the improvement of the place. The cathedral of the church, in this depopulated city, is a ſolid fabric, with a magnificent ſteeple, of no mean architecture. The Saracens deſtroyed and burnt this place about the year 840, and it has never ſince been able to recover itſelf. The coaſts of the iſland abound with ſardines and mackrel. N. lat. 44° 56′. E. long. 14° 35′.—Alſo, a town of Dalmatia, capital of the above iſland, the ſee of a biſhop, ſuffragan of Zara.

OSFAN, or Asfan, a town of Arabia, in the province of Hedsjas; 35 miles N.N.W. of Mecca.

OSIANDER, Andrew, in *Biography*, was a native of Bavaria, and born in 1498. He ſtudied at Wittemburg and Nuremburg, and was one of the earlieſt diſciples of Luther, and, like his maſter, frequently declaimed with great applauſe and ſucceſs againſt the corruptions of religion as introduced into the papal ſyſtem of doctrine and worſhip. Nor did he ſtop here, but moſt zealouſly ſupported the reformer in his attacks on the power and juriſdiction of the Roman pontiff, and in his efforts to eſtabliſh a faith and diſcipline more conſonant with the principles and precepts of the goſpel than thoſe of Rome. From this time he had a conſiderable ſhare in the controverſies and conferences which were held on the ſubject of religion. He took an active part at the conference of Marpurg in 1529, between Luther and the Swiſs divines, on which occaſion, however, he ſhewed that he thought and acted for himſelf; he ſpoke, after Luther, upon the ſubject of Juſtification, and maintained doctrines very diſſimilar from his. He was appointed miniſter and profeſſor at Konigſberg, where he became diſtinguiſhed for his peculiar notions on the ſubject of Juſtification, which he ſaid was effected in us by the union of God with our ſouls. This doctrine was oppoſed by many eminent doctors of the Lutheran church, but Oſiander was not to be deterred by any human authority, and juſtified himſelf with ſpirit, acuteneſs, and powerful talents, and his ſentiments were ſupported by perſons of conſiderable weight. He drew up a confeſſion of faith, which was printed by order of the duke of Brandenburg, but highly diſapproved by the Lutheran divines aſſembled at Augſburg. While he was preparing to maintain his doctrines, and to cruſh his opponents, he was attacked with an epileptic diſorder, which terminated his life in 1552. He wrote "Harmonia Evangelica;" "Epiſtola ad Zuinglium de Euchariſtia;" "Diſſertationes duæ, de Lege et Evangelio et Juſtificatione;" "Liber de Imagine Dei, quid ſit." He had a ſon Luke who was a Lutheran miniſter, and wrote an inſtitution of the Chriſtian religion, and other works, and who died at Tubingen in 1604; and there was another perſon named Luke Oſiander, who was chancellor of Tubingen, who died in 1638, and who left behind him a treatiſe "On the Omnipreſence of Chriſt as Man."

Osiander, Andrew, grandſon of the Andrew above-mentioned, was born at Blauberen, in the duchy of Wirtemburg, in 1562, and became a Lutheran miniſter. He was diſtinguiſhed for his early genius, and attachment to letters, paſſing through the different courſes of academical ſtudy, with the moſt honourable teſtimonials from his ſuperiors. In 1584 he was appointed deacon of the church of Aurach; whence he removed in 1586, and was made paſtor of the church of Gigligen. Afterwards he was appointed preacher and counſellor to prince Lewis of Wirtemburg, and in 1592 he received the degree of doctor of divinity in the new ducal univerſity of Tubingen. In the year 1598, prince Frederic nominated him abbot of Adelberg, and ſuperintendant of the churches in that diſtrict. In 1605 he became paſtor of the church of Tubingen, and was inſtalled chancellor of the univerſity in that place. He died in 1617. He was the editor of "Biblia Sacra, Latinè vulgata, cum Emendationibus et Explicationibus ſuperiorum Verſionum, et Obſervationibus ex Theol. Andreæ, Herbrandi," which paſſed through five editions in a few years, and is highly commended by father Simon, in his Crit. Hiſt. of the Old Teſtament. He was likewiſe author of ſeveral theological works.

Osiander, John Adam, a Lutheran divine and profeſſor, was a native of Vayingen, in the duchy of Wirtemburg, and was a provoſt of the univerſity of Tubingen, where he died in the year 1697. He is known as the author of "Commentarius in Pentateuchum," in five volumes, folio; alſo of Commentaries on Joſhua, the book of Judges, Ruth, and the two books of Samuel; of "Diſputationes Academicæ in præcipua et maxime controverſa Novi Teſtamenti Loca," and other learned works.

OSIANDRIANS, in *Eccleſiaſtical Hiſtory*, a ſect among the Lutherans ſo called from Andrew Oſiander, a celebrated German divine.

Their diſtinguiſhing doctrine was, that a man is juſtified formally, not by the faith and apprehenſion of the juſtice of Jeſus Chriſt, or the imputation of our Saviour's juſtice, according to the opinion of Luther and Calvin; but by the eſſential juſtice of God.

Osiandrians, *Semi*, were ſuch among the Oſiandrians, as held the opinion of Luther and Calvin with regard to this life; and that of Oſiander, with regard to the other; aſſerting, that man is juſtified here by imputation; and hereafter by the eſſential juſtice of God.

OSICA, in *Geography*, a town of Poland, in the palatinate of Sandomirz; eight miles S.W. of Lucko.

OSIER, in *Botany*. See Salix.

Osier, in *Planting*, a particular ſort of willow which is often planted in moiſt boggy ſituations on the borders of rivers, for the uſe of the ſhoots in baſket-making and other purpoſes.

The following are the names and uſes of the ſpecies which are employed in the vicinity of Brentford, as ſtated in the Middleſex Report:

"1. The *ſalix vitallina*, or yellow willow, which is cultivated chiefly by the nurſerymen, and being of a tough yielding nature, is uſed for binding packages of trees and ſhrubs in the drawing ſeaſon, and for tying up the branches of wall and eſpalier trees.

"2. The *ſalix amygdalina*, or almond-leaved willow, which is a ſpecies of which there are ſeveral varieties, one of which is called by the planters 'the ſmall red willow,' or 'binding rod;' it being chiefly uſed for binding the produce of garden-grounds. Another kind of this willow is at preſent known by the looſe appellation of the 'new kind;' it is of large growth, and produces a great crop; is uſed both by the baſket-makers and the corn ſieve-makers, and is fit for any work which requires a firm as well as a tough rod.

"3. The *ſalix viminalis*, or oſier willow. Of this ſpecies there are alſo ſeveral varieties, which are called among the planters by the name of 'the yellow and brown oſiers,' or 'Coomb's oſiers.' They are chiefly uſed by the baſket-makers, being very pleaſant working rods, and, as they produce a great crop, are much cultivated.

"Theſe three deſcriptions comprehend the moſt uſeful varieties, and the moſt profitable in point of crop, of any that are cultivated in that diſtrict. There is, however, a coarſe ſort of willow, known by the name of 'the Spaniard;' but whether it is a diſtinct ſpecies or not is not decided; it might be rendered extremely uſeful in counties where much bruſh or underwood is bound."

Mr. Young ſays "February is the proper time to plant oſiers and other ſorts of willows. No part of the farmer's buſineſs pays better than ſuch plantations, eſpecially if he has any low, ſpongy, boggy bottoms near a ſtream. The land ſhould be formed by ſpade-work into beds, ſix, eight, or ten feet broad, by narrow ditches; and if there is a power of keeping water in theſe cuts at pleaſure by a ſluice, it is in ſome ſeaſons very advantageous to do ſo." John Phillips, eſq. of Ely, ſtates in the ſixteenth volume of the Tranſactions of the Society of Arts, &c. that he has "made many experiments on different ſoils, with the view of aſcertaining which are moſt appropriate to oſier plantations; and which, of the almoſt infinite variety of oſiers, are beſt adapted to the different ſoils; but as his plantations are *chiefly* in the fens, he has directed his attention more particularly to determine what ſpecies of oſiers are moſt profitable in a black peat ſoil, and which is the moſt advantageous way of planting them, and at what ſeaſon of the year. It would have been of much public utility if the baſket-makers had given a ſpecific deſcription of the beſt kind of oſiers, the planting of which they wiſhed to be encouraged by premiums. The planters would in that caſe have procured thoſe only; much expence would have been ſaved to other gentlemen as well as himſelf, and a very conſiderable addition would have been made in the plantations to the ſtock of the beſt oſiers which are imported from abroad. As we have no generic or ſpecific terms, he will endeavour to give a plain vulgar account of thoſe only which are ſelected by the moſt experienced planters in his neighbourhood. Oſier, in common, is a word of very indeterminate ſignification; it is certainly a ſpecies of the ſalix, but admitting of many varieties. He has endeavoured to reduce them to two claſſes; firſt, thoſe which are ſo called by the growers and baſket-makers, diſtinguiſhable by their more blunt, mealy, or downy leaf; and ſecondly, thoſe that have a leaf more pointed, ſmooth, and green, reſembling that of a myrtle. Of the firſt claſs he has nine or ten varieties, all of which he ſhall eradicate, ſave one, *viz.* that which is called the *grey*, or *brindled oſier*. It has, in common with the others, the light-coloured leaf, but is known by having its bark ſtreaked with red, or blood colour. It has not been long introduced into this country. It grows vigorouſly, is very hardy and tough, and bleaches well. All the others of the firſt claſs delight in a wet ſoil, and will flouriſh even in the moſt barren kind of peat; but they are coarſe and ſpongy, have a large pith, are brittle, and very periſhable; they are, however, uſed ſometimes for the ſtouter parts of large baſkets, and unpeeled for wine-hampers. They grow quick and large, and a ſmall number will fill the ell bunch, by which all oſiers are ſold; they are profitable to thoſe growers only who live near London, or whoſe plantations are contiguous to water-carriage. He has ſome acres of them; and were he to ſend them there by waggon, which is the only mode of conveyance, they would not pay for the carriage. In time of war, when our intercourſe with France and Holland has been interrupted, where they grow better ſorts, they have been too much reſorted to, which has brought our baſkets into diſrepute, and leſſened the demand for them in foreign markets; this, together with the enhanced price of inſurance, accounts for the fact, that war makes oſiers in this kingdom both dear and cheap; that 'is, dear at the commencement for want of importation, and cheap during its progreſs, for want of exportation, after having been manufactured into baſkets and other works, to which they are applied."

And "of the ſecond claſs are, 1, the Welſh, both red and white; the red having the preference, and is ſaid to have been brought originally from Wales; they form an almoſt eſſential part of every plantation, as no other is fit to tie the bunches after the rods have been peeled and whitened. A bunch is formed by compreſſing the oſiers in an iron hoop or band, of an ell in circumference; eighty bunches make a load, which four years back ſold at 18*l.*; it is not now worth 12*l.* The beſt land will produce a load on an acre, but half a load is not a very bad crop on bad land. The expence of weeding, renewing, cutting, and peeling, is about 5*l. per* acre, when the buſineſs is well done; but they often go unweeded, when they are ſold at a low price, to the great decay of the plantations. The *Welſh* are alſo uſed to tie reed ſheaves for thatch; they are ſo bitter that cattle will not browſe them, unleſs driven to the extremity of hunger, and rats will not touch them, although they will deſtroy almoſt every kind of bandage. They were formerly grown for the coopers, to bind their hoops; but for this uſe they have long given way to the hazel; they are very tough and durable, and would rank with the beſt ſorts for the uſe of baſket-makers, were they of a better colour when peeled." And "2. The *weſt country Spaniard*, which is ſuppoſed to have been firſt introduced into the weſt of England from Spain. It is very different from the *Spaniard*, which is a ſpecies of the larger willow, and uſed for hedging-wood and hurdles. In the Iſle of Ely it was long in high eſtimation, until others were introduced, ſuppoſed to be ſuperior in ſome of their qualities; the bark is of a blueiſh-grey colour: it grows ſtout and ſtately, and objects to no ſoil; the grower, however, urges againſt it what he thinks to be a ſtrong objection, *viz.* that it produces a ſmall crop. It bears, comparatively, only a few ſhoots on a head; this is certainly true; but what then? it is not ſo profitable. He admits it, provided only an equal number be planted on an acre with thoſe that bear more ſhoots; but why ſhould the grower tie himſelf to plant an equal number of different ſorts on a given quantity of land? The nurſeryman is governed by no ſuch rule; and the farmer would become an object of pity, were he to ſow an equal quantity of every ſort of grain on an acre. The planter and farmer ſhould be guided only by the burden which the land is capable of bearing. His experience teaches, that an acre of land will carry, of this ſort, 14,000 plants, with more eaſe than 12,000 of the beſt new kind. 3. He has not been able to learn where the *new kind* originated. It is well known every where; and although it muſt be much older in ſome counties than others, it is univerſally called by that name. There are, however, two ſorts; the other is called the *laſt*, or *beſt new kind* The bark of the former is of a light brown colour; that of the latter reſembles ruſty iron, with light longitudinal ſtripes; it is on that account called, by ſome perſons, the *corderoy*. When the new kind was firſt introduced into the Iſle of Ely, it ſoon expelled moſt of thoſe of the firſt claſs; the few that are retained are uſed by the fiſhermen to make grigs, or twig tunnels, to catch eels and other fiſh: it ſtill maintains conſiderable reputation, but yields to the *laſt* new kind, which, beſides poſſeſſing moſt of the beſt properties, produces, on an average, at leaſt four ſhoots on the head more than any other, and it will grow well on a dry mellow ſoil. As its ſhoots are more numerous, a greater ſpace ſhould be allotted to it, to draw nouriſhment from the earth, and to admit the rays of the ſun and circulation of air, ſo neceſſary

neceſſary to the growth of every plant; 11,000 an acre is quite ſufficient on good land. But the beſt of all, conſidered in a public or political view, is, 4, the *French*. Under this name the *ground-ſetter* is, he ſuppoſes, frequently ſold; and he is informed, that it was ſo called, from its tendency, when neglected, to direct its ſhoots amongſt graſs and weeds, parallel with and near the ground; it is of the ſame quality, colour, and appearance with the French, except that it has at the point a tuft formed of leaves curled inwards, which has the appearance of a ſmall withered roſe-bud. You will eaſily know both from all others, thus: draw them through your fiſt from top to bottom, and the leaves will ſnap off with the brittleneſs of glaſs. The ground-ſetter grows very ſlowly, and is rejected by the planters on that account; the French, although more luxuriant, is alſo of comparatively ſlow growth; and it requires a great number to make up the bunch; but it is exceedingly taper, pliant, cloſe-grained, tough, and durable. The baſket-makers are more deſirous of it than any other, as it is beſt ſuited to make the ſmaller and finer baſkets, hats, fans, and other delicate articles. As it is much diſregarded by the planters in this kingdom, the baſket-makers, in times of peace, import vaſt quantities from France, the Auſtrian Netherlands, and Holland, where it is cultivated with great ſucceſs. It is ſingular, that it ſhould be imported cheaper than our planters can afford to grow it; the lands in France and Holland are much dearer than our fens. As an article of commerce, or as a raw material, it deſerves every encouragement that the public or individuals can give it; and if it be not ſo profitable to the grower, it is always of ready ſale."

He has alſo heard of another ſort, which is well ſpoken of, called the *red Kent willow*; but he is doubtful whether he is poſſeſſed of it or not; they have in this neighbourhood a very hard, tough willow, of a reddiſh colour, of which hurdles, cribs, &c. are generally made. He planted it laſt year, in foot-ſets, for the uſe of baſket-makers; but as the experiment is only in proceſs, he can ſay nothing of its utility.

Planting.—The following is the method of planting practiſed in theſe caſes, on the banks of the Thames, as deſcribed in the Tranſactions of the Society for the Encouragement of Arts, &c.

"The ground is dug during the winter a full ſpade's depth, and left rough, to prevent the tides from running it together again before it can be planted.

"The work begins in the month of March. The planter having procured the ſets or plants, which are fifteen or ſixteen inches long, cut diagonally off the ſtrongeſt ſhoots of the laſt year's growth, care being taken that they are not cut near to the top of the rods, that part being too porous to make a ſound plant, the ground is then marked out into rows two feet aſunder; and the ſets are ſtuck in the rows, eighteen inches from each other, leaving about ſeven inches of the ſets above the ground. This work is very eaſily done, without uſing even a dibble or a ſetting-ſtick; but, when planted, care muſt be taken, by hoeing, to keep them as free from weeds as poſſible; or if the ground be too wet for the hoe, a weeding hook may be uſed to keep them down: this is abſolutely neceſſary to enſure a good plantation. It is alſo equally neceſſary to keep the ground well drained, to prevent the tides remaining upon it any conſiderable time, for on that alſo depends the firmneſs and good quality of the rods.

The willows are cut over the firſt year with a bill-hook; the ſhoots are cut off cloſe to the ſtock and bound up in bundles, or boults, as they are called, which meaſure forty-two inches round, at ſixteen inches above the butt ends. The ſame proceſs of weeding muſt be purſued every ſummer; while they are ſhooting up from the ſtem. The next ſeaſon a cutting portion of them is left to ſtand another year, where large ſtuff is wanted for the ribs of large baſkets, &c.

"The planting of willows is expenſive in the firſt year; but if well managed they produce a great profit, as they improve in quantity every year."

But in regard to the moſt advantageous modes of planting, there is in the above volume of the Tranſactions of the Society of Arts, &c. a diverſity of opinion. The different qualities of ſoils are not ſufficiently attended to. A ſingle experiment is liable to deceive; what may hit or fail one year, may be the contrary the next. "It requires a diverſified ſeries of experiments to enable us to form a right judgment. The plantations of the year 1794, made on banks of ſoil thrown out of the ditches on each ſide, and thoſe made on the level ground, flouriſhed equally well that year. It was difficult to judge of them the next year, for they had been more or leſs injured by the vaſt inundation of all the fens of the Iſle of Ely, and which was not removed in many places until late in the ſummer; but in the third year the advantage was manifeſtly in favour of thoſe which had been made on banks or elevated beds. They have in this diſtrict from ten to fourteen inches of vegetating ſoil on the ſurface; immediately beneath it is a black or brown barren peat, of a looſe texture. In the drought of ſummer, when the moiſture is exhaled from the upper and more tenacious ſoil, the water inſtantly filters through the peat, and leaves the plants deſtitute of their beſt nouriſhment; but when the peat is thrown upon the ſolid earth, it will prevent the rays of the ſun from penetrating to the bottom; and when the water falls in the ditches, the lower and more tenacious ſoil will retain a ſufficient quantity of it for the uſe of the plants. Care ſhould be taken to inſert the ſets through the peat into this lower ſtratum; they will ſtrike their radicles the firſt year into this more ſolid earth; but when the peat has been meliorated by the ſun and air, and been compreſſed, and become more adheſive, they will ſtrike higher in the ſtem, until the radicles or fibres approach the ſurface. It muſt be admitted, that this is an expenſive method, and leſſens the quantity of land to be planted upon. To remedy this inconvenience, the writer lays out his land in beds or barrows, of eighteen feet wide; ditches of nine feet wide are dug on each ſide; the top of which, fourteen inches thick, is laid on the barrows; turf for fuel is then dug in the ditches, the expence of which is about 1*s.* 8*d.* a thouſand; they are ſold for 2*s.* 6*d.*

The beds or barrows, now conſiſting of about two feet and a half thick of ſolid earth, above the ſurface of the peat, are planted the following autumn, and produce good crops; when the water is ſufficiently low, he caſts upon theſe beds a fetid vegetable ſubſtance, vulgarly called bear's muck; it reſembles wet ſhag tobacco, and lies under the peat; it is extremely uſeful to the plants; and although it is, in its primitive ſtate, a perfect caput mortuum, when expoſed ſome time to the air it putrifies, affords mucilage, and becomes a good manure. In embanked diſtricts, ſubject to frequent and long inundations, two other advantages are obtained from theſe raiſed beds; the oſiers are thereby removed farther from the reach of the ice, which on a thaw floats into the lower plantations, and does them much injury. When the waters are high, in the cutting or planting ſeaſon, the beds are more acceſſible than the level ground; but having had the command of the water laſt ſummer, by a mill or engine, he dug out the peat into turf, having firſt laid

laid aſide the upper ſpit; the turf being removed, he ſhall return this ſpit into the ditch, and plant upon it; thus no ground will be loſt."

It is further ſtated, that "in the year 1796, he made an experiment on an acre of land of this quality; he ploughed one half of it, and the other half was dug with the ſpade, about fourteen inches deep; the ſod of that thickneſs was inverted by the ſpade. The plantation on the ploughed land was very weak, and failed in many places; that which followed the ſpade did better; but they are both ſo bad, that they muſt be renewed this year. On the former, the beſt land lay uppermoſt, which, when deprived by the heat of its moiſture, derived no aſſiſtance to ſupport the plants from the peat that lay underneath; on the latter, ſome of the beſt land was laid in the ground, but not deep enough to retain a ſufficient quantity of moiſture. The preceding year he planted in a piece contiguous, on banks as before deſcribed, and there the oſiers do well. And he has a rich loam lying on a bed of potters' clay; the ſituation is low, and expoſed to the water; French oſiers were very ſcarce, and he could procure only a few hundreds laſt year; determined to eke them out as far as he could, he laid them down in their whole length, and pegged them on the ground; they ſtruck good roots into the earth, and threw out abundant ſhoots. This experiment, together with that of planting upon banks, will enable him to anſwer the queſtion often aſked, 'Of what length ought the ſet to be?' It depends entirely upon the nature and ſituation of the land. There ſhould be ſo much of it in the ground as to enable it to procure moiſture, and ſo much of it out of the ground as to make it acceſſible in the cutting ſeaſon, where much weeding is not required; and where there are no floods, or where they ſubſide quickly, there ought to be very little of it out of the ground. The nouriſhment, in that caſe, will paſs immediately from the roots to the rods or ſhoots, without the burden of firſt ſupplying the head or ſtock."

Seaſon of Planting.—In reſpect to the time of planting, every experiment he has made confirms the opinion, that the "autumn, and not the ſpring, is the moſt proper ſeaſon for planting. Thoſe who think with him ſay, that the fall of the leaf indicates the proper time to cut the ſets; it certainly is ſo in general; but the leaf of the oſier, like that of the oak and other trees, will ſometimes prolong its departure. The ſtagnation of the juices is the true criterion by which to judge, not on account of the ſet, but of the trunk, leſt, if you amputate it whilſt the juices are in circulation, it ſhould bleed to death. He has planted in the firſt week of October, and the ſets appeared to remain torpid for the remainder of the year; about Chriſtmas he took up ſeveral of them, and was much pleaſed to find that they had ſtruck root, although they had given no outward appearance of vegetation from the time of planting. It is probable that the earth retains a ſufficient portion of the ſummer heat until the autumn, to give life to plants at the root, when the atmoſphere may at that time be ſo cold as to diſcourage any exertions above-ground; and perhaps nature may be more vigorous when her operations are confined to one point. It is added that, when you plant in ſpring, the ſet ſeems (if he may ſpeak ſo figuratively) to have its attention diſtracted by two operations not very homogeneous, the one upwards, the other downwards. It is impelled to ſhoot its radicles into the earth, to form its ſtability, and procure ſuſtenance; and it is called upon at the ſame time to put forth its leaves and branches. To ſpeak without a figure, the prolific ſun and air induce it to exhauſt the juices, in extending the ſhoots before the roots are ſufficiently ſtrong and large to ſupply the drainage; hence it is that, contrary to the commonly received opinion, a warm and dry ſpring is always injurious to the young plantations. If there be not ſufficient rain to convey ſuſtenance by the leaves and bark, in aid of the ſmall quantity procured by the root, the plant muſt die or dwindle, and it is very obſervable, that the firſt vigour of the late-planted ſet is a ſure prognoſticator of its decline or diſſolution. In the autumn of 1795 he made a ſmall plantation, and on the remainder of the piece he planted in March following. In the beginning of May, thoſe laſt planted were the forwardeſt, which, for a time, ſtaggered his opinion of the moſt proper time for planting; but in June, thoſe planted in the autumn had much the advantage, and have continued to grow well: thoſe that were ſet in the ſpring decayed in ſummer, and many of them died. When the fibres have been formed before the winter, or when a tendency to form them has been obſerved, by the ſwelling of the bark, and particularly at the eye, the plant is enabled to charge itſelf with a ſufficient portion of the juices to anſwer the demand of ſpring; the rule, therefore, which he lays down for himſelf, where no obſtructions are raiſed by the water, is to plant as early in the autumn as he can cut the ſets, without endangering the parent ſtock."

In the fifth volume of the Farmer's Magazine the following method is ſtated to be had recourſe to: in the fens many holts (as they are provincially called), or plantations of oſiers, are raiſed, which beautify the country, keep the ſtock warm in the winter, and provide much uſeful wood for baſkets, cradles, and all kinds of wicker-work, and alſo for cribs for cattle to eat ſtraw or hay out of, or to make ſtows or hurdles to fence in ſtacks, part lands, &c. &c.; or they make hedges that laſt four years well, and if allowed to grow five years, many of them would make fork-ſhafts for hay and corn. Theſe holts or plantations of oſiers are commonly made in the middle of the land, in the north and eaſt corners, and ſometimes at any end, ſide, or place, that appears moſt eaſy, or in any reſpect the moſt deſirable. The ſituation and ſize of the holts vary exceedingly. Sometimes they are made in the middle of lands, from 10 to 60 yards ſquare, and in others, in the ſides or ends of, from 1 yard wide to 11, and from 10 to 100 yards long.

The mode of planting is very ſimple; it is, firſt to dig the land from 6 to 12 inches deep, and then to prick down cuttings of four years' growth, and 18 inches long, at about three feet diſtance from each other. The ſoil ſhould be moor or clay, or any thing that is low and wet; if drowned half the year it will be but little the worſe.

Theſe holts or oſier plantations muſt be fenced round, either with dykes, which is the moſt common, or with hedges, as is the moſt convenient. The proper ſeaſon for making them (they ſeldom fail of growing at any time) is from the fall of the leaf till very late in the ſpring, and the ſets are very cheap. Such plantations are cut annually for baſkets, ſkeps, ſcuttles, cradles, and all kinds of wicker-work, but when the oſiers are kept for ſets, or to make hedging wood, or for ſtows or hurdles, they are cut only once in four years.

Wherever the farmer has lands that are ſuited to this ſort of cultivation, as there is a conſtant demand for ſuch articles, he ſhould never neglect making plantations, as nothing that he can put upon ſuch land will probably pay him ſo well.

Mr. A. Young ſtates, that "the late Mr. Forby, of Norfolk, knew the value of theſe plantations well for various purpoſes. Oſiers planted in ſmall ſpots, and along ſome of his hedges, furniſhed him with hurdle-ſtuff enough to make many dozens every year, ſo that he ſupplied himſelf entirely with that article, as well as with a profuſion of all ſorts of baſkets, eſpecially one kind that he uſed for moving cabbage-plants, for which purpoſe they were much better

than tumbling the plants looſe in a cart. The common oſier he cut for this purpoſe at three years, and that with yellow bark at four."

OSIMO, in *Geography*, a town of the marquiſate of Ancona, the ſee of a biſhop, anciently a city of Umbria, named "Auxinum;" 12 miles S.S.W. of Ancona. N. lat. 43° 38′. E. long. 13° 36′.

OSIO, Teodato, in *Biography*, is the author of a curious ſpeculative tract, publiſhed at Milan in 1637, entitled "L'Armonia del rendo parlare, con ragione di numeri Pitagorici diſcoperta da Teodato Oſio," or, the harmony of common ſpeech or ſimple proſe and verſe, eſtabliſhed by the power of arithmetic, of muſical ſpeculations, and the Pythagorean ratio of numbers.

We procured this little book with great eagerneſs, in hopes that we ſhould find ſome acute and ingenious reflections on recitative, with nice diſcriminations between common ſpeech, narrative melody, and air. But in the moſt ample and minute index we ever ſaw to ſo ſhort a tract, the word recitative never occurs. And, indeed, when this book was publiſhed, its forms and phraſeology were hardly ſettled. The new dramas, called operas, had only been performed occaſionally at the grand duke's court, and private repreſentations at Florence. So that in 1637, the reſt of Italy ſcarcely knew of the exiſtence of a *muſica rappreſentativa*, or recitative, which was neither ſinging nor ſpeaking, but the intermediate utterance or emiſſion of vocal ſound, between both. The firſt opera at Venice was performed in 1637, the preciſe period of ſignor Oſio's publication, which is written in an obſcure and myſterious ſtyle, bordering on pedantry; nor is it eaſy to ſay, after peruſal, what is the author's object.

Osio, in *Geography*, a town of Sweden, in Eaſt Gothland; 32 miles W.S.W. of Linkioping.

OSIRIS, in *Mythology*, one of the great gods of the Egyptians, to whom they paid their chief worſhip. Oſiris was ſuppoſed to repreſent the ſun, and Iſis the moon.

Some writers in theology have ſuppoſed, that all the other deities of the Egyptians were only attributes of Oſiris and Iſis. See Isis and Orus.

The worſhip of Bacchus among the Greeks was formed upon that of Oſiris, as we learn from many paſſages in Diodorus Siculus. (See Bacchus) Oſiris was among the Egyptians the ſymbol or emblem of the ſun, which was the firſt object of their idolatry, and Iſis was that of the moon; and it is ſaid that their names refer to thoſe luminaries, ſince in their language Oſiris denotes "one who ſees clear," and Iſis the "ancient," an expreſſion which among them ſignified the moon. All the learned agree, that the oxen Apis and Mnevis, conſecrated to Oſiris after his apotheoſis, were the ſymbols of the ſun. Thus, whether it was that the Egyptian prieſts, to cover the hiſtory of this prince from the eyes of the people, gave out that he was really the ſun, or whether acknowledging Oſiris to have been a mortal man who had governed Egypt, and conferred many bleſſings upon it, they were willing to paſs it upon the world, that his ſoul was gone to reſide in that orb, ſtill they agreed that he was now become that radiant luminary, who by the benign influences of his beams, diffuſes fertility and plenty over all, and that to him vows, prayers, and ſacrifices were to be addreſſed. Thus was the worſhip of Oſiris confounded with that of the ſun, and that of Iſis, with that which was paid to the moon. In this way the prieſts had found the art of making idolatry leſs groſs, by ſaying it was not a mortal man, but an eternal ſtar, which was the object of public adoration. It appears that the Egyptians ſometimes conſidered Oſiris and Iſis as real perſons, who had governed Egypt with conſummate wiſdom, and at other times as beings of an immortal nature, who had framed the world, and ranged matter into the form which it ſtill retains. Thoſe who ſuppoſe that they had been human perſons, agreed that they were brother and ſiſter; but they differ about their parents. The moſt common opinion is that reported by Diodorus Sieulus, who ſays, that the Sun was the firſt who reigned in Egypt; that he was ſucceeded by Vulcan, and Vulcan by Saturn, who having married Rhea, his ſiſter, had by her Iſis and Oſiris. The Egyptian mythology with regard to theſe fancied deities is ſtated by ſome writers in the following manner. The Egyptians, ſeeing good and evil equally prevalent in the world, and not being able to conceive that a being eſſentially good ſhould be capable of permitting evil, and much leſs be the author of it, were the firſt who invented two principles, the one good, the other bad, and introduced this error which afterwards ſo generally prevailed. The good principle they repreſented under the name of Oſiris, and the bad one under that of Typhon; hence ſprung the wars and perſecutions of the latter againſt his brother, whom he afterwards cut off. As they attributed all the evil that exiſted in the world to Typhon, ſo they conſidered Oſiris as the author of all the good. The creation of the world, for a long time diſputed and retarded by the machinations of the evil principle, together with the order and harmony that prevailed in it, was the work of Oſiris; and all the wars and troubles, and kinds of evils that ravage the univerſe, proceeded from Typhon. The good principle, according to the repreſentation of Plutarch, founded on ancient traditions, poſſeſſed three qualities, of which the one performed the office of father, and this was Oſiris; the other that of mother, who was Iſis; and that of ſon, who was Orus, the firſt production of the father and mother. (See Orus.) Some authors have alleged that Oſiris was Joſeph, and others maintain that he was Moſes; whilſt it is aſſerted by others, that this king of Egypt was more ancient than they, and that his worſhip was eſtabliſhed in their time through all Egypt, ſince the Iſraelites imitated its ceremonies in the adoration of the golden calf.

Banier is of opinion, that Oſiris is the ſame as Mizraim, the ſon of Ham, who peopled Egypt ſome time after the deluge, and who, after his death, was deified; and he is called by the ancients the ſon of Jupiter, becauſe he was the ſon of Ham, or Hammon, whom he himſelf had acknowledged as a god. Marſham takes Oſiris to have been Ham himſelf, known under the name of Menis at the head of the dynaſties, which ſucceeded to the gods and demigods. Indeed the learned in general allow, that Oſiris was one of the firſt deſcendants of Noah by Ham, and that he governed Egypt, whither his father had repaired, and there founded a ſmall kingdom, a few years after the diſperſion which happened in the time of Peleg. Diodorus aſſerts, that this prince is the ſame with Manes, the firſt king of Egypt; and perhaps at his apotheoſis his name was changed to that of Oſiris. For other particulars we refer to the article Isis.

The learned Jablonſki deduces the term Oſiris from Oſchiri, denoting "he who makes time." Accordingly it is alleged, that the Egyptian aſtronomers, after repeated obſervations, regulated the year by the courſe of the ſun; that the ſolar year was eſtabliſhed by the academy of Heliopolis, 1325 years B. C., 320 after the departure of the Iſraelites; and that the prieſts, who till that time had honoured the ſun under his proper name of "Phrá," beſtowed on him, in commemoration of ſo important an event, that of Oſiris, or author of time. Savary's Letters in Egypt, vol. ii.

OSITH, or Osyth, *St.*, in *Geography*, an iſland of England,

land, at the mouth of the Blackwater river, or Malden water, in the county of Eſſex, with a village. It is ſaid to have changed its name from Chiche to that of St. Oſith, who was a virgin, murdered here by the Danes, and canonized. A monaſtery of black Auguſtine canons was founded here to her memory by Richard Beaver, biſhop of London, in the year 1120. In 1801 St. Oſith contained 1268 inhabitants; 11 miles S.E. of Colcheſter.

OSIUS, in *Biography*, biſhop of Cordova, in Spain, was born in 257. He became the friend of Conſtantine, who by his perſuaſions convened, in 323, the council of Nice, where Oſius preſided. Under the emperor Conſtantius he was ſo much perſecuted, that he turned Arian. It ſhould however be mentioned, that he was then very aged, being almoſt, or entirely, 100 years old. Having made his recantation, he was permitted to return to his dioceſe, where he died ſoon after, extremely penitent, and in his laſt moments renounced the Arian hereſy with great fervour.

OSIUS, FELIX, a learned Italian, was born at Milan in 1587, and became profeſſor of rhetoric at Padua, where he died in 1631. His principal works are, 1. Romano-Græcia. 2. Tractatus de Sepulchris Epitaphiis Ethnicorum et Chriſtianorum. 3. Elogia Scriptorum illuſtrium; and ſeveral other works, in high eſtimation at the period in which he flouriſhed.

OSKIN, in *Agriculture*, a provincial word uſed to ſignify an ox-gang; or a quantity or ſhare of common field-land, proportioned probably to the ſize of the fields and number of meſſuages in the given townſhip, at the time the fields were ſet out or appropriated among the houſes.

OSKIPARO, in *Geography*, a town of Perſian Armenia; 36 miles N.W. of Kanja.

OSKOL, a town of Ruſſia, in the government of Kurſk; on the river Oſkol; 60 miles S.E. of Kurſk. N. lat. 50° 50′. E. long. 37° 14′.

OSKOVA, a mountain of Boſnia; 20 miles S.E. of Serajo.

OSLAWA, a town of Moravia, in the circle of Brunn; 12 miles W. of Brunn.

OSLEOM IRON, in the *Wire Works*, a particular ſort of bars of iron, wrought on purpoſe for the manufacture of iron wire. Theſe are ſmall and ſquare, and the firſt thing done with theſe, towards the making them into wire, is the ſtraining, or drawing them at a furnace to ſmall rods, of the thickneſs of one's little finger; theſe they bow round, and deliver them to the wire-drawers. See WIRE.

OSMA, in *Geography*, an almoſt ruined town of Spain, in Old Caſtile, on the Duero, the ſee of a biſhop. In the year of Rome 682, it took part with Sertorius, and was deſtroyed by Pompey. In 931, the Moors were defeated here by the Chriſtians; 40 miles S.E. of Burgos. N. lat. 41° 45′. W. long. 2° 58′.

OSMAN, TOPAL, in *Biography*, a diſtinguiſhed Turkiſh general, was born in 1673. He was brought up among the youth of the ſeraglio deſtined to public employments, and by his proficiency in learning languages, and in military exerciſes, and his amiable diſpoſition, obtained the eſteem of his maſters. He was appointed ſuperintendant of the carriages, and in 1698, or 9, he was ſent to Cairo with a meſſage from the emperor. In his paſſage the veſſel in which he had embarked was attacked by an Algerine cruizer, and taken after an action, in which Oſman, while fighting with great bravery, was dangerouſly, but not mortally, wounded in the arm and thigh. The conſequences of the latter wound rendered him lame for life, and obtained for him the name of *Topal*, which ſignifies *halting*. The prize was carried into Malta, where it was viſited by Vincent Arniaud, a native of Marſeilles, then poſt-captain. Oſman, on his coming on board, ſaid to him, "Do a generous action—ranſom me—you will be no loſer by it." Arniaud aſked the captain what he demanded for the ranſom of this ſlave, to which the captain replied, "a thouſand ſequins." Arniaud now turned to Oſman; "I," ſaid he, "never ſaw you before in my life; I know nothing of you, and you aſk me to pay a thouſand ſequins for you on your bare word." "Both of us," ſaid Oſman, "act in character. For myſelf, I am in fetters, and it is natural that I ſhould employ every means to regain my liberty. You naturally diſtruſt my faith. I have no ſecurity to give but my word, in which you have no reaſon to confide; if, however, you will run the riſk, you will not repent it." Arniaud immediately agreed with the captain for five hundred ſequins, which he paid down, and putting Oſman on board a bark of his own, ſent him medical aſſiſtance, and afforded him every means neceſſary for his recovery. When perfectly recovered, Oſman propoſed to write to Conſtantinople for remittances to pay the debt, and deſired to be diſmiſſed upon his parole. Arniaud immediately allowed him to take the bark, and diſpoſe of it as he pleaſed. He immediately ſet ſail for Damietta, whence he aſcended the Nile to Cairo. He there paid to the captain a thouſand ſequins, on account of his benefactor, and made him a handſome preſent for himſelf. He executed his commiſſion, returned happily to Conſtantinople, and was himſelf the bearer of the news of his captivity. His gratitude to his deliverer never forſook him, and during all the ſteps of his elevation, he never intermitted a correſpondence of letters and of preſents with him. He even extended his beneficence to all the Frenchmen with whom he had any concern. In 1715, in the war between the Turks and the Venetians, the grand viſier, Ali-Baſhaw, intending to invade the Morea, aſſembled his army in the neighbourhood of the iſthmus of Corinth, and gave in charge to Oſman to force the paſſage, which he effected, and at the ſame time carried the city of Corinth by ſtorm. He acted as ſecond in command at the ſiege of Corfu, in the following year; and when it was raiſed, he remained three days after the general, to favour the retreat of the troops, not withdrawing till they were in ſafety. He was appointed Seraſkier, or chief commander in the Morea, in 1722, on which occaſion he requeſted Arniaud to ſend him one of his ſons, that he might give him a lucrative employment. He was next nominated to the government of Romelia, having obtained firſt the dignity of baſhaw of two tails, and now of three tails. In 1731 Oſman was called to the high dignity of grand viſier: he immediately cauſed Arniaud to be informed of this promotion, who, with his ſon, viſited Conſtantinople on the occaſion, bringing with him twelve Turkiſh captives, whom he ranſomed. The viſier received them in the preſence of the great officers of the empire, to whom he related the ſtory of his benefactor's generoſity to him. He treated them with the moſt affectionate familiarity, and gave them ſome ſubſtantial proofs of his kindneſs. His reign as viſier was of ſhort duration; he was depoſed in 1732, more to the regret of the people, to whom he had reſtored plenty, than to his own; and he felicitated himſelf that he left his place with a good conſcience, and without forfeiting the regard of his ſovereign. On his road to the government of Trebiſond, to which he had been appointed, he was ordered to take the command of the Turkiſh army in Perſia. In July 1733, he fought a bloody battle with Thomas Kouli-Khan, in which the Ottoman arms were victorious, and the Perſians were ſaid to have loſt 60,000 men. His ſucceſs was rewarded with an acceſſion of power and dignity. In a ſecond battle, which was extremely diſaſtrous to the Turks, Kouli-Khan took

took his revenge, and Oſman was killed by two muſket-ſhots. This was in the month of September, 1733. Moreri. Univer. Hiſt. Frazer's Life of Nadir-Shah, &c.; 1742.

Osman I., emperor of the Turks, was the ſon of Achmet I., and ſucceeded his uncle Muſtapha in 1618. He declared war againſt Poland in 1621, but after ſeveral defeats, he was obliged to conclude a diſadvantageous peace. Attributing his want of ſucceſs to the Janiſſaries, he reſolved to ſubſtitute a militia of Arabs in their room, which ſo provoked them, that they depoſed him, and placed Muſtapha on the throne, who cauſed Oſman to be ſtrangled in 1622. Oſman II. ſucceeded his brother Mahomet in 1754, and died in 1757.

Osman *Aga*, in *Geography*, a town of Walachia; 22 miles S.W. of Galacz.

OSMANDGIK, a town of Aſiatic Turkey, in the government of Sivas; 140 miles N.W. of Sivas. N. lat. 40° 45′. E. long. 35° 10′.

OSMANTHUS, in *Botany*, a name given by Loureiro to the *Olea fragrans*, alluding to its odoriferous flowers. See Olea.

OSMERI, in *Ichthyology*. See Salmo.

OSMI, in *Geography*, a town of Dagheſtan; 28 miles N.W. of Deſbund.

OSMITES, in *Botany*, a Linnæan genus, whoſe name, derived from *οσμη, a ſmell*, or *ſavour*, is expreſſive of its very powerful odour. Linn. Gen. 441. Schreb. 575. Willd. Sp. Pl. v. 3. 2258. Mart. Mill. Dict. v. 3. Juſſ. 186. Lamarck Dict. v. 4. 647. Illuſtr. t. 704. Gærtn. t. 174. (Bellidiaſtrum; Vaill. Mem. Par. 1720.)—Claſs and order, *Syngeneſia Polygamia Fruſtranea*. Nat. Ord. *Compoſitæ Diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* imbricated, gibbous; the inner ſcales elongated at the point. *Cor.* compound, radiated; *florets* of the diſk perfect, numerous, tubular, five-cleft; thoſe of the radius female, ligulate entire. *Stam.* (in the perfect florets) Filaments five, very ſhort; anthers cylindrical, tubular. *Piſt.* (in the perfect florets) Germen oblong; ſtyle thread-ſhaped, the length of the floret; ſtigma cloven: the female or ligulate florets differ in having a ſmaller germen and an obſolete ſtigma. *Peric.* none, except the unchanged calyx. *Seeds*, of the perfect florets, ſolitary, oblong, with ſcarcely any crown; or bordered, with an obſolete, ſomewhat chaffy one; in the female florets moſtly abortive or imperfect rudiments. *Recept.* chaffy.

Eſſ. Ch. Receptacle chaffy. Down obſolete. Florets of the radius ligulate. Calyx imbricated, ſcaly.

1. O. *Bellidiaſtrum*. Linn. Sp. Pl. 1285. (Anthemis fruticoſa; Amoen. Acad. v. 4. 330.)—Leaves linear, downy. Stems ſcarred.—Native of Ethiopia.—*Stem* ſhrubby, ſcarred by the fallen *leaves*, which are awl-ſhaped or linear, triangular, in tufts, at the ends of the branches, ſeſſile, downy all over. *Flowers* terminal, ſeſſile, ſeveral together at the ends of the ſtem and branches, their diſk yellow, and radius white.

2. O. *dentata*. Willd. n. 2. Thunb. Prodr. 163.—Leaves obovate, toothed, villoſe.—A native of the Cape of Good Hope, adopted on the authority of Thunberg. We are not acquainted with either a deſcription or figure of this ſpecies.

3. O. *camphorina*. Linn. Sp. Pl. 1285. Mant. 477. Gærtn. t. 174. (Bellis camphorifera africana aquatica, flore albo; Seb. Muſ. v. 1. 143. t. 90. f. 2.)—Leaves lanceolate, ſerrated from the baſe.—Found alſo at the Cape of Good Hope.—*Stems* quite ſimple, waved, furrowed, each bearing a ſingle head of flowers. *Leaves* alternate, ſeſſile, deeply ſerrated or toothed, naked, gradually ſmaller towards the top, much reſembling thoſe of *Chryſanthemum Leucanthemum*, the Ox-eye Daiſy.—*Flowers* capitate, terminal, with a yellow diſk and white radius.—The whole plant has a very ſtrong camphoric odour, whence its name.

4. O. *Aſteriſcoides*. Linn. Sp. Pl. 1285. (Leucanthemum fruticoſum camphoratum, foliis craſſis, anguſtis acutis; Burmann. Afric. 161. t. 58. f. 1.)—Leaves ovato-lanceolate, downy, dotted, obſoletely ſerrulated.—Native of the Cape.—*Stem* thick, branched, warty. *Leaves* alternate, thickly ſet, ſlightly embracing the ſtem. *Flowers* capitate, terminal, ſeſſile, yellowiſh-white.—The ſmell of camphor is not ſo ſtrong in this ſpecies as in the preceding.

5. O. *calycina*. Linn. Syſt. Veg. ed. 14. 783. Suppl. 380. (Lapeirouſia calycina; Willd. Sp. Pl. v. 3. 2260. Thunb. Prodr. 163.)—Leaves lanceolate, naked. Calyx remarkably ſcaly.—Like all the preceding ſpecies, a native of the Cape of Good Hope.—*Stem* ſhrubby, erect, proliferous, not thickened; branches a little downy. *Leaves* ſcattered, erect, narrow, lanceolate, naked or ſlightly downy, ſtriated, veined beneath. *Flowers* terminal, ſeſſile, yellow.

See Dr. Smith's reaſons for retaining this laſt ſpecies as an *Oſmites*, under the article Lapeirousia of this work.

OSMIUM, in *Chemiſtry*, a ſimple ſubſtance, and one of the metals. We have already ſtated, under the article Iridium, that when the black powder, which remains after diſſolving platina from the grains, as they come from South America, is alternately treated with an alkali and an acid, two ſolutions are obtained. The acid ſolution contains the iridium, while the alkali contains the metal called oſmium.

For the diſcovery of this metal we are indebted to Mr. Tennant. Fourcroy and Vauquelin had previouſly made ſome experiments upon the black powder above alluded to, but it ſeems they had confounded the two metals which it afforded.

The alkaline ſolution from the black powder contains the oxyd of oſmium, to which it gives a yellow colour.

In order to obtain the oxyd pure, the alkaline ſolution muſt be put into a retort. When ſulphuric acid is added, and heat applied, the oxyd comes over, diſſolved in water, to which it gives a ſtrong ſmell and a ſweetiſh taſte.

If the black powder be heated with nitre in a retort, at a temperature a little ſhort of redneſs, the oxyd of oſmium riſes and condenſes in the neck of the retort, in the form of oil. On cooling, it concretes into a ſemi-tranſparent maſs.

This ſubſtance is ſoluble in water, and poſſeſſes ſimilar properties to that obtained from the alkaline ſolution. It holds its oxygen with ſo little affinity, that if mercury be ſhaken with either the alkaline or the aqueous ſolution, the metal is ſet free, and forms an amalgam with the mercury. If the mercury be diſtilled from the alloy without contact with the air, the oſmium remains in a ſtate of purity. Oſmium is of a dark blue-grey colour, having metallic luſtre. This laſt property, together with its forming an alloy with mercury, ſufficiently prove its metallic nature.

When heated in the open air, it appears to evaporate. It is not, however, the pure metal which evaporates, but this occurs, in conſequence of its combining with the oxygen of the atmoſphere, ſince the metal is not volatile when the oxygen is excluded. When it is heated ever ſo ſtrongly in a cloſe crucible lined with charcoal, it does not fuſe.

The moſt remarkable property of this metal is its not being oxydated by any of the acids, although it eaſily combines with the oxygen of the atmoſphere, and with that ariſing from the decompoſition of nitric, above ſtated.

It is not leſs curious that it ſhould be oxydated and diſſolved

by potaſh. Although the oxyd of this metal is ſoluble in water, and its affinity for oxygen ſmall, it does not change vegetable blues, nor exhibit any other acid properties.

The ſolution of oxyd of oſmium, like that of gold and ſilver, ſtains the ſkin permanently.

An infuſion of galls changes it to a purple colour, which ultimately becomes blue.

If ether or alcohol be added to the aqueous ſolution, the oxyd is decompoſed, and the metal precipitated: a ſimilar effect would no doubt take place by paſſing hydrogen, or ſulphuretted hydrogen gaſes, through the ſolution.

This oxyd is decompoſed by all the metals excepting gold and platina. The other metals being immerſed in the ſolution of this oxyd, ſoon deprive it of its ſmell, while the oſmium is precipitated in the metallic form.

We are indebted to Mr. Tennant for theſe facts, which he made out at the time he diſcovered the metal. It is to be regretted that no new facts have been added, by which we might know the proportion of its combinations with other bodies.

OSMOND, in *Biography*, a ſaint, was born in Normandy, of a noble family. In 1066 he followed the fortunes of William, who became the conqueror of England, and who made him the chancellor of this kingdom, and nominated him to the biſhopric of Saliſbury. He reformed the liturgy for his dioceſe, which form afterwards became general throughout the kingdom, under the name of the Saliſbury liturgy. He died in 1099, and was canonized by Calixtus III.

Osmond *Royal*, or *Flowering Fern*, in *Botany*. See Osmunda.

Osmonds, in our *Old Writers*, a kind of iron anciently brought into England. It is mentioned in ſtat. 32 Hen. VIII. cap. 14.

OSMORZKOI, in *Geography*, a town of Ruſſia, in the government of Kolivan, on the Irtiſch; 201 miles W.S.W. of Kolivan. N. lat. 53° 15′. E. long. 76° 14′.

OSMUNDA, in *Botany*, a word of which no explanation has ever been given, and which Linnæus, in his *Philoſophia Botanica*, 160, mentions as one of thoſe which can hardly be traced to any language. In this he was miſtaken; for *Oſmund* is a Saxon proper name for a man, and expreſſes domeſtic peace. Its application to the plant is found to have originated in England. The elegant *Filix florida*, or Flowering Fern, which firſt received it, and which is an aquatic plant, ſhould ſeem, by Gerarde's herbal, a type or memorial of ſome "Oſmund, a water-man," whoſe hiſtory had not come down, even to that old writer, but whoſe heart, he ſays, was commemorated in the core of the root. Linn. Gen. 559. Schreb. 756. Mart. Mill. Dict. v. 3. Swartz Syn. Fil. 160. Ind. Occ. 1578. Sprengel. Crypt. 174. t. 5. f. 38. Tourn. t. 324. Juſſ. 15. Lamarck Illuſtr. t. 865. f. 2. Brown. Prodr. Nov. Holl. v. 1. 163. (Todea; Willd. in Mem. of the Acad. at Erfurt, for 1802. 14. t. 3. f. 1. Swartz Syn. Fil. 162.)—Claſs and order, *Cryptogamia Filices*. Nat. Ord. *Filices*. Linn. Juſſ.

Eſſ. Ch. Capſules ſtalked, nearly globoſe, ſemibivalve, burſting from the baſe up to a ſtriated dorſal protuberance, crowded on the back of the frond, or compoſing aggregate ſpikes on its contracted ſubdiviſions.

Obſ. From this the genus of *Botrychium*, conſiſting of the Linnæan *O. lunaria* and others which, like it, have bivalve capſules, without either ring or ſtriated protuberance, and growing on a proper ſtalk diſtinct from the leafy part of the frond, is now ſeparated. Their habits are unqueſtionably diſſimilar.

* *All the fronds fertile.*

1. O. *Claytoniana*. Virginian Oſmunda. Linn. Sp. Pl. 1521.—Frond pinnate, clothed when young with ruſty down; leaflets deeply pinnatifid; ſome of them, ſcarcely diminiſhed, covered with capſules.—Gathered by Clayton in Virginia. Sent, in 1772, by Samuel Martin M.D. to Kew garden, where it ſtill flouriſhes, bearing fruit in the latter part of ſummer. The *fronds* are upright, a yard high, narrow, compoſed of numerous, ſhort, moſtly alternate, deeply pinnatifid *leaflets*, ſmooth when fully grown. Many of theſe, about the middle of the frond, are either totally or partially covered with innumerable brown *capſules*, the edges of each ſegment turning in, ſo that nothing but capſules appear on either ſide of the leaf.—*O. interrupta* of Michaux Boreal-Amer. v. 2. 273, though adopted by Swartz on the credit of the French author, ſeems by his definition to be preciſely the *Claytoniana*.

2. O. *regalis*. Oſmund-royal, or Flowering fern. Linn. Sp. Pl. 1521. Sm. Fl. Brit. 1108. Engl. Bot. t. 209. Bolt. Fil. 6. t. 5. Fl. Dan. t. 217. (Filix florida, ſive Oſmunda regalis; Ger. em. 1131.)—Frond doubly pinnate; leaflets ſomewhat heart-ſhaped at their baſe; the upper ones contracted and covered with capſules. Native of Europe and North America, in marſhy ſhady places. An elegant fern, conſpicuous for its aſh-like *leaves*; and copious, compound, ruſty-coloured, cluſters of *capſules*, crowning the ſummit of the frond.

3. O. *barbara*. African Oſmunda. Thunb. Prodr. 171. Brown. Prodr. Nov. Holl. v. 1. 163, by accident, we preſume, printed *barbata*. (O. totta; Swartz in Schrad. Journ. for 1801. 105. Acroſtichum barbarum; Linn. Sp. Pl. 1529. Filix africana, floridæ ſimilis, in ambitu foliorum argutè denticulata; Pluk. Phyt. t. 181. f. 5. Todea africana; Willd. Mem. Erf. for 1802. 14. t. 3. f. 1. Swartz Syn. Fil. 162.)—Frond doubly pinnate, coriaceous, ſmooth; leaflets decurrent, confluent, ſomewhat ſerrated; the lower ones unchanged, bearing capſules.—Native of the Cape of Good Hope, and of New South Wales. We obtained a fine living ſpecimen, in June 1806, from the ſtove of Mr. Evans, at Stepney. This fern is evidently a congener of the *Oſmundæ*, in our firſt diviſion more particularly. Its *frond* is handſome, two feet high, light green, ſmooth and ſhining, of a broad oblong figure, the *branches* and *leaflets* cloſe and regular; the latter elliptic-oblong, bluntiſh, ſometimes an inch in length, all decurrent into the winged ſtalk. Several of the *leaflets* neareſt the main ſtalk, about the middle of the frond, are covered at the back with crowded elliptical maſſes of *capſules* of a ruſty brown, unaccompanied by any pubeſcence.

** *Fertile fronds ſeparate.*

4. O. *cinnamomea*. Woolly Oſmunda. Linn. Sp. Pl. 1522. (Filix non ramoſa, latiùs dentata mariana; Pluk. Mant. 78. Phyt. t. 400. f. 1.)—Fronds pinnate; leaflets deeply pinnatifid, with a woolly ſtalk; the fertile ones contracted and woolly.—Native of North America. It flouriſhes in Kew garden, having been received at the ſame time with the firſt ſpecies, from which it is known by its more woolly and cinnamon-coloured aſpect, and by ſome of the *fronds* being entirely fertile, the others barren. The ſegments of the *leaflets* too are ſhorter and broader; the cluſters of *capſules* hairy.

5. O. *japonicum*. Japan Oſmunda. Thunb. Japon. 330. Swartz n. 5. (Dsjemmai, Phyllitis foliis ramoſis: Kæmf. Am. Exot. 891.)—Fronds doubly pinnate; leaflets lanceolate, ſerrated, heart-ſhaped at their baſe; the fertile ones triply pinnate.—Found

—Found on hills in Japan, in April and May, by Thunberg, who deſcribes it as very like *O. regalis*, except the fertile *fronds* being ſeparate from the barren ones.—Swartz cites a figure of this in Houyttin's Nat. Hiſt. v. 2. t. 96. f. 1. which we have not ſeen.

O. *lancea*. Narrow-leaved Oſmunda. Thunb. Japon. 330. Swartz n. 6. Houytt. Nat. Hiſt. v. 2. t. 95. f. 1. *Sw*—Fronds doubly pinnate; leaflets lanceolate, ſerrated; the fertile ones repeatedly compound, in a ternate manner.—Gathered by Thunberg in April and May in the Japaneſe iſland of Nipon. The firſt diviſions of the *frond* are nearly oppoſite, eſpecially the upper ones; *leaflets* alternate, rarely almoſt oppoſite lanceolate, very finely ſerrated, tapering at each end, ſmooth, an inch or inch and half long.

OSNABRUCK Township, in *Geography*, the fourth townſhip in the county of Stormont, in Upper Canada, in aſcending the river St. Lawrence. In front of this townſhip is the rapid called the Long Sault.

OSNABURG, or Osnabruck, *Biſhopric of*, a principality of Germany, bounded on the N. and W. by the biſhopric of Munſter, on the E. by the counties of Ravenſberg and Diepholz, and principality of Minden, and on the S. by the county of Ravenſberg; about 40 miles long, and from 16 to 24 wide. Almoſt a moiety of this biſhopric conſiſts of heath-lands, which yield turf and paſturage. The beſt ſpot is about Quackenbruck, and is called "Artland." It produces rye ſufficient for the inhabitants, and 500 ſtills. It imports from the principality of Minden, and the county of Schauenburg, conſiderable quantities of buck-wheat, ſmall wheat, oats, and barley. It has but a ſmall breed of cattle. It has little wood, but beſides turf, it yields coal. It has a ſalt-work at Diſſen; and plenty of marble. In the whole country are four principal towns, and three ſmaller, and about 20,000 fire-places, or hearths, uſually accommodating two families. The noble and free are not reckoned in this account. The land-ſtates are the chapter, the knights, and the principal towns. The land-diets are appointed by the biſhop, and held in the town of Oſnabruck. The inhabitants are induſtrious, and of the peaſants, about 6000 go yearly to Holland, where they mow, till, cut turf, and do other work for hire. The religion of this country is partly Roman Catholic, and partly Lutheran. No Jews are tolerated. The principal and moſt profitable occupation of the inhabitants conſiſts of ſpinning of yarn, and of manufacturing a coarſe kind of linen for Guinea and America, from which they derive an influx of about 1,000,000 rix-dollars. This biſhopric is the firſt and oldeſt in Weſtphalia, having been founded by the emperor Charlemagne. At the peace of Oſnabruck, in 1648, it was ſettled that this biſhopric ſhould have alternately a Roman Catholic and a Lutheran biſhop; and that the latter ſhould be always ſelected out of the houſe of Brunſwick Luneburg, and from among the poſterity of duke George, and on the failure of theſe, out of the poſterity of duke Auguſtus. On the ſettling of the indemnities at Ratiſbon, in 1802, it was agreed that the biſhopric ſhould devolve on the electoral houſe of Brunſwick in perpetuity, on condition that the king of England, as elector of Hanover, ſhould reſign all pretenſions to Hildeſheim, Corvey, and Hexter, and abandon his rights in the cities of Hamburgh and Bremen, &c. By the peace of Tilſit, the new kingdom of Weſtphalia was eſtabliſhed, and Oſnaburg annexed to it.

Osnaburg, a city of Weſtphalia, in the biſhopric of the ſame name, ſeated on the Haſe, and fortified after the ancient manner. It conſiſts of the Old and New Town, under the government of a common magiſtracy. The number of houſes, excluſive of the public and bye-buildings, amounts to 1200; but the town is not populous. Its magiſtracy is Lutheran, and annually choſen. The Roman Catholics and the Lutherans have each two pariſh churches. Oſnabruck was formerly one of the Hanſe towns. Its principal ſubſiſtence depends upon its linen-trade, and the retail of foreign manufactures. This was the firſt town in Weſtphalia which received the Lutheran doctrine. George I. king of England died in this town in his way to Hanover; 24 miles N.N.E. of Munſter. N. lat. 52° 17′. E. long. 7° 4′.

Osnaburg *Iſland*, a ſmall iſland in the South Pacific ocean, ſuppoſed to have been firſt diſcovered by Quiros, in 1606, who called it "Dezana;" by Bougainville, it was called "Boudoir," and by Capt. Wallis, who diſcovered it in 1767, it was called Oſnaburg: by the natives it is denominated "Maitea." It is a high round iſland, not above a league in circuit; in ſome parts covered with trees, in others a naked rock. It has no anchoring-place. The inhabitants were clothed, and appeared to be of an humane diſpoſition; they were numerous and uſed canoes; ſome hogs were ſeen. Capt. Cook viſited this iſland in the year 1769, S. lat. 17° 48′. W. long. 148° 10′.—Alſo, an iſland in the South Pacific ocean, diſcovered by Capt. Carteret in the year 1767. It is a ſmall, low, flat iſland, appearing almoſt level with the water's edge, and covered with green trees. S. lat. 22°. W. long. 141° 34′.

Osnaburg *Houſe*, a ſettlement of the Hudſon's Bay company in North America, ſituated at the N.E. corner of lake St. Joſeph, 100 miles W. by S. of Glouceſter houſe. N. lat. 51°. W. long. 90° 15′.

OSNABURGHS, a kind of coarſe linen imported from Germany: of which there are two kinds; the one white, and the other brown. The manufacture of the white is well underſtood in our own country; but the method practiſed in Germany of manufacturing the brown ſort, and of giving it its peculiar colour, is not known. Some have ſuppoſed, that it depends on the manner of bleaching the flax, and others on that of bleaching the yarn after it is ſpun.

OSOKOLSKA, in *Geography*, a town of Ruſſia, in the government of Archangel, on the river Mezen; 104 miles E.N.E. of Archangel.

OSOLA, a town of the iſland of Sardinia; 14 miles N.N.E. of Saſſuri.

OSONALA, a town of Naples, in Abruzzo Ultra; 10 miles E.S.E. of Aquila.

OSORIO, Jerome, in *Biography*, a learned Portugueſe prelate, who flouriſhed in the ſixteenth century, was born at Liſbon in the year 1506. From his earlieſt childhood he diſcovered a ſtrong inclination for acquiring learning, and aſtoniſhed his maſters by the rapidity with which he became ſuch a proficient in the Latin language as to be able to converſe in it. At the age of thirteen he was ſent to the univerſity of Salamanca, where he perfected himſelf in Latin and Greek, and afterwards, by the command of his parents, applied for ſome time to the ſtudy of the civil law. When he was nineteen years old he removed to Paris, where he ſtudied under the moſt celebrated profeſſors in that city. Here he became intimately acquainted with Peter le Faire, one of the firſt aſſociates of Loyola, a circumſtance that contributed to the early introduction of the Jeſuits into Portugal, by inducing him warmly to recommend the patronage of the ſociety to king John III. Oſorio went from Paris to Bologna, where he devoted himſelf entirely to the ſtudy of divinity, the ſcriptures, and the Hebrew language. After his return to his native country, he was appointed by the king profeſſor of ſacred literature at the univerſity of Coimbra, where he gave lectures on the epiſtle of St. Paul to the Romans, and alſo on the prophecy of Iſaiah. He was now ordained prieſt, and was appointed to the benefice of Tavara.

He received other inſtances of church preferment, and was at length promoted to the biſhopric of Sylves by Catherine of Auſtria, the duties of which high office he performed with the utmoſt regularity and benevolence. When king Sebaſtian arrived at his majority, he determined to attempt the conqueſt of Africa, againſt which Oſorio earneſtly admoniſhed and humbly entreated the king, foreſeeing and predicting the diſaſtrous conſequences that would neceſſarily reſult from it. When he found his remonſtrances unavailing, he went under various pretences to Rome, that he might not be a witneſs to the calamities which he was ſenſible were impending over his country. He was favourably and reſpectfully received by pope Gregory XIII. Sebaſtian, though he would not follow the advice of his prelate, could not bear that he ſhould be abſent from his country, and recalled him to Portugal within twelve months of his departure. He returned, and almoſt immediately received the fatal intelligence of the deſtruction of his ſovereign and his army in the battle of Alcazar againſt the Moors. (See SEBASTIAN.) We cannot enter into the miſeries in which the conſequences of that battle involved Portugal, particularly after the death of king Henry. On this laſt event, Oſorio, always the friend of peace, adviſed ſubmiſſion to the claims of Philip II., king of Spain, to the crown, and he laboured to preſerve the people of his dioceſe from taking a part in the tumults which diſtracted and laid waſte the kingdom. Theſe diſorders he took ſo much to heart, that it is ſaid he died with grief in the year 1580. He is highly ſpoken of by Dupin, who ſays "he wrote with eaſe and eloquence. He is entitled to the denomination of the *Portugueſe Cicero*, ſince no writer has more cloſely imitated that Roman, whether we regard his ſtyle, his choice of ſubjects, or his manner of treating them." His works are numerous, partly political and partly theological. The latter chiefly conſiſted of paraphraſes on Job, the books of Pſalms, the book of Wiſdom, and Iſaiah; and Commentaries upon ſeveral of the books of the Old Teſtament. His object in his paraphraſes and commentaries, is not ſo much to explain the terms of the text as to extend the ſenſe of it, and to ſhew its order and ſeries. Theſe works, with twenty-one ſermons, were collected together, and publiſhed at Rome in 1592, in four volumes, by his nephew Jerome, canon of Evora, who alſo wrote a life of his uncle, which he prefixed to the collection of his works; "Notationes in Hieronymi Oſorii Paraphraſim Pſalmorum," printed in the third volume of the above-named collection. The work, ſays Mr. Southey, in the General Biography, by which the biſhop of Sylves is beſt known, in his hiſtory "De Rebus Emmanuelis, Luſitaniæ Regis," of which a new edition appeared in 1791 at Coimbra, in three volumes 12mo. Of this work, which is beautifully printed, there is a French tranſlation and an Engliſh one. The kings of Portugal, as their hiſtory was more ſplendid than that of all others, ſeem to have been of all ſovereigns moſt deſirous that it ſhould be extenſively known. Purſuant to their deſire, two hiſtories in Latin of the diſcovery of India, and the conqueſts there, appeared about the ſame time, one by the Jeſuit Maffæus, and the other, this work, by Oſorio. The library of Oſorio was carried off to England by the Engliſh fleet, on their return from Cadiz, in 1596. The Bodleian library was opened the enſuing year, and lord Eſſex gave ſir Thomas Bodley a conſiderable part of this collection. Moreri. Gen. Biog.

OSORRO, in *Geography*, a town of Chili, in a diſtrict abounding with gold mines, 40 miles S.E. of Valdivia. S. lat. 40°. W. long. 73° 40'.

OSOSOR, a word uſed by ſome authors as a name for opium.

OSPEDALETTO, one of the four renowned conſervatorios at Venice, of which Sacchini was the maſter in 1770. The females educated there were all orphan girls; one of them, La Ferrareſe, had a voice of uncommon compaſs at that time, as ſhe was able to reach the higheſt E in our keyed-inſtruments, upon which ſhe could dwell a conſiderable time, in a fair natural voice. But beſides this natural power, ſhe had been well taught, and was, in every reſpect, a very capital ſinger. We heard at this conſervatorio a Latin oratorio, "Macchabæorum Mater," compoſed by Sacchini, in an exquiſitely graceful and pathetic ſtyle. In the performance of this ſacred drama, the Ferrareſe gratified us ſtill more in delivering an admirable accompanied recitative with ſuch energy and feeling as are ſeldom heard.

OSPREY, in *Ornithology*. See FALCO *Oſſifragus*.

OSRHOENE, in *Ancient Geography*, a ſmall ſtate of Aſia, which occupied the northern and moſt fertile part of Meſopotamia, between the Euphrates and the Tigris. Under the Seleucidæ, a part of this country took the name of Mygdonia, with the title of kingdom. Polybius ſpeaks of this kingdom in connection with Antiochus the Great. The capital of this kingdom was *Edeſſa*; which ſee. The feeble ſovereigns of Oſrhoene, placed on the dangerous verge of two contending empires, were attached from inclination to the Parthian cauſe; but the ſuperior power of Rome exacted from them a reluctant homage, which is ſtill atteſted by their medals. After the concluſion of the Parthian war under Marcus, it was judged prudent to ſecure ſome ſubſtantial pledges of their doubtful fidelity. Forts were conſtructed in ſeveral parts of the country, and a Roman garriſon was fixed in the ſtrong town of Niſibis. During the troubles that followed the death of Commodus, the princes of Oſrhoene attempted to ſhake off the yoke; but the ſtern policy of Severus confirmed their dependence, and the perfidy of Caracalla completed the eaſy conqueſt. Abgarus, the laſt king of Edeſſa, (A.D. 216.) was ſent in chains to Rome, his dominions reduced into a province, and his capital dignified with the rank of colony; and thus the Romans, about ten years before the fall of the Parthian monarchy, obtained a firm and permanent eſtabliſhment beyond the Euphrates.

OSRUSHNAH, in *Geography*, a town of Turkeſtan, and capital of a diſtrict, to which it gives name; 65 miles N.N.E. of Samarcand. N. lat. 40° 30'. E. long. 64° 30'.

OSSA, in *Anatomy*, a technical term employed in ſpeaking of the bones, particularly of the head, as oſſa naſi, oſſa ſpongioſa, &c. See BONE and OS.

OSSA, in *Geography*, a river of Pruſſia, which runs into the Viſtula, 15 miles below Culm.

OSSABAW, an iſland in the Atlantic, near the coaſt of Georgia, 20 miles in circumference. N. lat. 31° 42'. W. long. 81° 17'. Between this iſland and Great Waſſaw is a channel, called Oſſabaw ſound. N. lat. 31° 43'. W. long. 81° 12'.

OSSÆI, or OSSENI, a name ſometimes given to the Jewiſh ſect of religion called Eſſenians.

OSSARA, in *Geography*, a town of Hindooſtan in Mohurbunge; 18 miles N. of Harriopour.

OSSAT, ARNAUD D', *Cardinal*, in *Biography*, was born in 1536, of parents in humble life, at a village near Auch: he was left an orphan at an early age, and roſe in the world wholly by his own merit and induſtry. Entering into the ſervice of a young nobleman of the houſe of Marca, he ſtudied with him, and in time became his preceptor. In 1559 he took his pupil, with two other young perſons, to Paris, where he carefully ſuperintended their education, at the ſame time taking care not to neglect his own ſtudies. In philoſophy he was a diſciple of Ramus, and compoſed a

work in his maſter's defence. After he had made what he deemed ſufficient progreſs in his legal ſtudies, he practiſed at the bar in Paris, and was greatly admired for his maſculine eloquence. He obtained the poſt of a counſellor in the preſidial court of Melun: after this he went with Paul de Foix, archbiſhop of Toulouſe, who had been nominated by Henry III. ambaſſador, to the court of Rome, as his ſecretary. After the death of that prelate, in 1584, Oſſat took holy orders, and was received into the houſe of cardinal d'Eſte. The ſecretary of ſtate, Villeroi, made him Chargè des affaires for the French court; and in this quality, at the beginning of Henry IVth's reign, he was highly ſerviceable in promoting the reconciliation of that king with the ſee of Rome. In 1598 he was honoured with a cardinal's hat, and in three years afterwards was made biſhop of Bayeux. He died in 1604. He was a man of great penetration, and ſingularly prudent and circumſpect in the management of affairs, ſo that it is ſaid of him, that he never made a falſe ſtep. He left behind him a great number of letters relative to the negociations in which he was engaged, which are reckoned models of political ſagacity. The beſt edition is that of Amelot de la Houſſaye, in 1698, in two vols. 4to., and five vols. 12mo. Moreri.

OSSEGG, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 18 miles W.N.W. of Leitmeritz.

OSSELET, in the *Manege*, is a very hard excreſcence, reſembling a little bone, on the inſide of the knee (and never on the outſide), appearing to be of the ſame ſubſtance with the reſt of the knee, and only diſtinguiſhable from the knee by its extending a little lower

OSSENIGA, in *Geography*, a town of Italy, in the Veroneſe; 6 miles N. of Verona.

OSSERVANZA, Ital., in *Muſic: con oſſervanza*, with care, attention, exactitude, in obſerving and executing with preciſion whatever is written or printed; without omiſſions or addition, which Corelli expreſſes by *come ſta*, as it ſtands in the copy.

OSSIACH, in *Geography*, a town of Carinthia, on the lake Oſſiacher; 4 miles S.W. of Feltkirchen.

OSSIACHER See, a lake of Carinthia, four miles long and two wide; 4 miles N.E. of Villach.

OSSIAN, in *Literary Hiſtory*, a Celtic bard, who, as well as Fingal and other heroes whom he is ſaid to have celebrated in his poems, is claimed both by the Highlanders of Scotland and the Iriſh. It is highly probable, that the name of Oſſian and his heroes would have been confined to theſe people, had not Macpherſon, about the middle of the laſt century, publiſhed two volumes of poems, as the genuine offspring of this Celtic bard. The circumſtances which he ſtated, as having attended the diſcovery of theſe poems, and the nature and deſcription of the poems themſelves, excited ſtrong ſuſpicions of their authenticity, almoſt as ſoon as they were given to the world: the controverſy to which theſe ſuſpicions gave birth, contributed to render them known and popular; however, it would be unfair to deny, that their intrinſic merits, though certainly very much miſrepreſented and overrated, alſo obtained them popular applauſe and favour. There were alſo other circumſtances, beſides the ſingular and ſuſpicious nature of their diſcovery and publication, and the poetic merits which they poſſeſſed, or were ſuppoſed to poſſeſs, which fixed on them the curioſity and intereſt of men of philoſophy and literature. They exhibited a moſt uncommon and unparallelled picture of human manners; a picture, which, if it were drawn from nature, would confound all the principles which philoſophy had deduced from the hiſtory of mankind: they alſo related events, not eaſily reconcileable to the authenticated hiſtory of the country, where the ſcene was laid: on theſe accounts, the intereſt of almoſt all claſſes was fixed upon them; they were admired by the lovers of poetry, who, in their admiration, had not time or inclination to inveſtigate their authenticity; while by thoſe who viewed them more coolly and philoſophically, and who could not permit themſelves to admire, before they were convinced of their authenticity, ſtrong and various objections were urged againſt their claim to be conſidered as the poems of Oſſian. The intereſt which they excited was ſtill farther increaſed, by the Highlanders taking up the queſtion, both reſpecting their authenticity and their poetical merits, as one in which their honour and pride were immediately and deeply concerned: they could not tamely or quietly abandon the belief that Oſſian wrote theſe poems; and when Macpherſon was charged with having forged them, the firm conviction they had expreſſed of their authenticity, joined to the diſgrace which, through Macpherſon, they thought would fall on themſelves, rendered them moſt obſtinate in their original belief.

In this article it is propoſed to examine whether Oſſian and his heroes were Scotch or Iriſh; to fix, as nearly as poſſible, the period during which they flouriſhed; to ſtate the notices of his poems, which are ſcattered in ancient authors; to give an account of the ſearch after them, which was made before the time of Macpherſon; to relate the circumſtances attending the publication of Oſſian's poems by Macpherſon; to point out the principal and moſt ſtriking characteriſtics of theſe poems; and to conclude with an abſtract of the controverſy reſpecting their authenticity.

Although the claims of the Highlanders to Oſſian and his heroes have been more urgent and repeated than thoſe of the Iriſh, there is good reaſon for believing that the latter poſſeſs the greateſt juſtice. There are numberleſs traditions in Ireland concerning the Fions, a ſpecies of militia, inhabiting Leinſter, and commanded by Fin Mac Coul: that this Fin Mac Coul is the ſame as the Fingal of Macpherſon is clear, from the identic name of the father, Cuwal, the ſon Oiſin, and the grandſon Oſkir; and from the old Scotch poets, who ſometimes call him Fingal, and ſometimes Fin Mac Coul. Among the warriors of this ancient militia, the Iriſh traditions and hiſtories hand down the names of Goll Mac Morn (Gaul the ſon of Morni) of Oſgur the ſon of Oiſin, evidently the Oſſian of Macpherſon, of Fergus O'Fillan, and other warriors. Oſſian himſelf, alſo, is celebrated among the Fions. Beſides theſe heroes, Iriſh traditions and ancient manuſcripts mention a military order in Ulſter of earlier date, the chief ornament and ſupport of whom was Cuchullin. This evidence undoubtedly aſcribes Oſſian and his heroes to Ireland; but it is farther corroborated, even by the traditions and old ſongs and poems of the Highlands, though the paſſages in the latter, which deſcribe Ireland as the native country of Oſſian, Fingal, &c. have been altered for controverſial purpoſes: it is needleſs to cite all theſe paſſages: the following, from Erſe poems, collected in the Highlands by Dr. Young, biſhop of Clonmore, and publiſhed in the firſt volume of the Iriſh Tranſactions, may ſuffice.

In the combat of Con, the ſon of Dargo, and Gaul ſon of Morne, the Fions are called "the noble Fions of Ireland:" this, in the Perth edition of this poem, is changed into "the nobles and great chieftains." In the combat of Oſgar, and Illan ſon of the king of Spain, for "the Fions of Ireland," the Perth edition ſubſtitutes the "noble Fions." In a poem called the Death of Oſcar, of which Macpherſon made uſe in the firſt book of Temora, Ireland is expreſsly mentioned as the country of that prince: "The death of Oſcar grieved my heart, our loſs is great in the prince

prince of the chiefs of Ireland:" and in another poem on this ſubject, ſtill current in the Highlands, Oſcar is called the "prince of Ireland; the prince of the heroes of fertile Ireland." Even ſo late as the time of Gawin Douglas, Ireland ſeems to have been regarded as the country of Fingal and the other heroes of Oſſian.

"Great Gow Mac Morn, and Fin Mac Coul, and how
They ſhould be gods in Ireland, as men ſay."

There is another circumſtance, which conſiderably ſtrengthens the opinion that the Fions were natives of Ireland. No Highlander ever heard of Selma, except through the poems publiſhed by Macpherſon; whereas, Almhuin is pointed out by every old Iriſhman as the abode of Fingal: the name of this place occurs frequently in the poems which were collected in the Highlands by Dr. Young; it is always mentioned as the palace of Fingal; neither Selma, nor any other place of reſidence, is given in theſe poems to this hero; and it is worthy of remark, that Macpherſon, in the uſe he has made of theſe poems, has either omitted altogether the name of Almhuin, in order that no trace of Fingal's real country might exiſt, or changed it into Albin, in order to countenance the idea, that he was a native of Scotland; as will appear from the following paſſages; "Greater love ſeized all the heroes of Fin of Almhuin." On this paſſage Dr. Young remarks: "The palace of Fin Mac Cumhal in Leinſter, was ſeated on the ſummit of the hill of Allen, or, rather, as the natives of that country pronounce it, Allowin; the village and bog of Allen have thence derived their name. There are ſtill the remains of ſome trenches on the top of the hill, where Fin Mac Cumhal and his Fions were wont to celebrate their feaſts. The country hereabouts abounds in wonderful tales of the exploits of theſe ancient heroes. Theſe two lines are omitted in the Perth edition." Iriſh Tranſactions, i. 76.

In the Dublin copy of the poem on the invaſion of Ireland by Erragon, which Macpherſon appears to have made uſe of in his battle of Lora, theſe words occur: "To Almhuin in Leinſter reſidence of the Fions, they took their voyage acroſs the ſea:" in this place, Macpherſon has ſubſtituted the word Albin, though, as Dr. Young remarks, there can be no excuſe for this alteration, "as the king of Lochlin is repreſented ſteering his fleet boldly to the coaſts of Ireland, and challenging the heroes of Innisfail. The infidelity, therefore, of the queen of Lochlin could not be ſaid to have been the cauſe of ſpilling Scottiſh blood, ſince the ſcene of the whole tranſaction is laid in Ireland, and they are the heroes of Innisfail who fell in battle."

As, therefore, the Iriſh traditions reſpecting the Fions are uniform and conſiſtent; as, even in the poems which celebrate their exploits, and which are current and popular in the Highlands, many paſſages occur, in which Ireland is expreſsly mentioned as their native country; and as, beſides, the palace of Fingal is a place not known in the Highlands, but ſtill pointed out, at leaſt by ſimilarity of name, in Ireland, we are juſtified in concluding that Oſſian and his heroes were natives of Ireland. This concluſion will be ſtill farther ſtrengthened if we examine the vague and inconſiſtent notices, which Scotch tradition and hiſtory records of Oſſian and his heroes. Indeed, in Scottiſh hiſtory they were never heard of till Bruce claimed them as of Scotch extraction; for in the paſſages quoted by the Highland Society (in their Report on the Poems of Oſſian), Fingal, and the other heroes of that bard, are mentioned, without any reference to the country of which they were natives. The Highland Society lay great ſtreſs on the proverbs which are current in the Highlands reſpecting Oſſian, and the names of places correſponding with the names of his heroes: *Oſſian dale*, blind Oſſian, is a perſon as well known there as ſtrong Sampſon, or wiſe Solomon: the very boys, in their ſports, cry out for fair play, "the equal combat of the Fingalians:" and "Oſſian, the laſt of his race," is proverbial to ſignify a man who has had the misfortune to ſurvive his kindred. In anſwer to the queries, which were tranſmitted by the Highland Society, ſeveral of their correſpondents mentioned the names of various places in their neighbourhood, tending to ſhew the univerſal ancient traditionary belief of the exiſtence of Fingal and his heroes. "Among many others were enumerated the well known cave of Staffa, firſt made known by the deſcription of ſir Joſeph Banks; the whirlpool, or gulf ſet down in Blair's Atlas Scotiæ, publiſhed A.D. 1662, called Coire Fin Mac Coul, or the Whirlpool of Fion, ſon of Comhal; and the hill in the iſle of Sky, known by the name of Ait Suidh Fhinn, or Fingal's ſeat. Indeed there are few diſtricts in the north-weſt of Scotland, where ſuch inſtances may not be found." Report on the Poems of Oſſian, p. 79.

But all theſe circumſtances, even when collected and taken together, do not amount to a proof that Oſſian and his heroes were natives of the Highlands of Scotland: they merely prove the antiquity of the tradition and belief reſpecting them. In Ireland, on the other hand, there are not only ſimilar proverbial and local notices (if the expreſſion may be allowed) of Oſſian and his heroes; but there is hiſtorical evidence that the Fions were Iriſh, and the palace of their chief is ſtill recogniſed and pointed out. None of the traditions, or genuine poems, preſerved in the Highlands, which have reference to them, name or claim them as natives of that country: whereas, in ſeveral paſſages of the latter, they are clearly and expreſsly declared to have been natives of Ireland, and to have reſided there, and there to have carried on their military exploits. But it may be aſked, how happens it, if Oſſian and his heroes were Iriſh, that the tradition of them is ſo ſtrong and prevalent in the Highlands, the proverbial expreſſions relating to them ſo marked and numerous, and the places named after them ſo common: the ſolution of this difficulty is very eaſy: it is well known, that at the period when the Fions lived, the intercourſe between that part of Ireland, where they are ſaid to have reſided, and the Highlands of Scotland, was frequent; and it is alſo highly probable, as will afterwards be ſhewn, that an Iriſh colony, nearly at, or immediately ſubſequent to this period, paſſed over to that part of the Highlands, where the traditions and notices of Oſſian are moſt commonly met with.

It is not very eaſy, accurately and ſatisfactorily to fix the period when Fingal and Oſſian flouriſhed: the era which Macpherſon aſſigns them muſt be given up. Later Iriſh MSS., traditions and poems, both in Ireland and the Highlands, repreſent Oſſian as contemporary with St. Patrick; but if we may depend on the account of the Iriſh militias of Ulſter and Leinſter, Fingal muſt have ſucceeded St. Patrick nearly two centuries; and, conſequently, his ſon Oſſian could not have been contemporary with him. According to the Iriſh annals (on the authenticity of which, however, much ſtreſs ought not to be laid), Fingal flouriſhed under Cormac O'Cuin, about the year 254. That Oſſian was not contemporary with St. Patrick, is, however, moſt ſatisfactorily proved from Jocelin, a writer of the 12th century, in his life of that ſaint, who places Fin Mac Coul above a hundred years before him. Oſſian and his heroes may, therefore, be placed about the end of the third and the beginning of the fourth century; and it may be inferred, that all poems which refer them to a later period, are not

the

the genuine poems of Oſſian. It will be proper to keep this remark in our recollection when we come to diſcuſs the authenticity of the poems which have been aſcribed to this bard.

There are ſcarcely any notices reſpecting theſe poems to be found in old authors, who treat either of Ireland or of Scotland: the bards or ſeanachies of the latter country do not trace up their kings to the Fions, or heroes of Fingal, but to the Dalriadic monarchs. At the coronation of Alexander III. a Highland genealogiſt is introduced by Fordun to recite the royal pedigree, but inſtead of aſcending from Fergus Mac Erth, to Erth Congal, Fergus, Fingal, and from thence, according to Oſſian, to Comhal, Trahal, and Trenmor, he proceeds through the whole race to Fergus I., a ſufficient proof, that there was no tradition then of the ſix kings of Morven, nor any poems, which treated of the exploits of Fingal and his heroes. Had theſe poems exiſted in the time of Monro, dean of the Iſles, he would have appealed to them in his genealogy of the clans. Buchanan indeed, in his account of the family of Buchanan, mentions the Militia of Fin, and ſpeaks of "rude rimes," on the actions of Fin Mac Coul, as retained by the Iriſh and Scottiſh Highlanders. There is, however, a paſſage in biſhop Carſwell's introduction to his tranſlation of the Forms of Prayer, into Gaelic, printed at Edinburgh in the year 1567, which is quoted in the report of the Highland Society, in order to give an idea of the general impreſſion and delight, which the recital of the poems or ballads (of Oſſian) produced among the inhabitants of the Highlands, which it may be proper to conſider: in this paſſage the biſhop complains, that "great is the blindneſs and ſinful darkneſs, and ignorance, and evil deſign of ſuch as teach, and write, and cultivate the Gaelic language, that with a view of obtaining for themſelves the vain reward of this world, they are more deſirous and more accuſtomed to compoſe vain, tempting, lying, worldly hiſtories, concerning the *Tuatha de dannan*, and concerning warriors and champions, and Fingal the ſon of Cumhall, with his heroes, and concerning many others, which I will not at preſent enumerate or mention, in order to maintain or reprove, than to write, and teach, and maintain the faithful word of God, and of the perfect way of truth." Now this paſſage, cited by the Highland Society, in order to prove the currency and popularity of Oſſian's poems, actually proves, that the bards were accuſtomed, in the time of biſhop Carſwell, to compoſe poems concerning Fingal, which poems were probably in ſubſequent ages conſidered as the genuine poems of Oſſian.

The firſt perſon who ſeems to have conceived the idea of collecting the poems and ballads of the Highlands, was a young man, Jerome Stone of Dunkeld, who had acquired a knowledge of the Gaelic language. Of one of the poems, which he collected, he publiſhed a tranſlation in rhyme, in the Scotch Magazine for January 1756. Nearly about the ſame time Mr. Pope, miniſter of Reay in Caithneſs, entertained the deſign of making a collection of the ancient poetry of the Highlands; but in conſequence of the death of the gentleman who engaged with him in this undertaking, he ſeems to have dropped it very ſoon.

The next collector of Gaelic poetry was Mr. James Macpherſon. In the year 1759, Mr. Home, the author of Douglas, met him at Moffat; in the courſe of a converſation on the manners of the Highlands, Macpherſon informed him that one of their favourite amuſements "was to liſten to the tales and compoſitions of their ancient bards, which he deſcribed as containing much pathos, and poetical imagery, and at Mr. Home's deſire, he tranſlated ſome fragments, which his memory ſerved him to recollect. The beauty of theſe fragments ſtruck Mr. Home, and his friends at Moffat, to whom he communicated them, ſo forcibly, that they prevailed on Mr. Macpherſon, who was rather averſe to the undertaking, to publiſh them in a ſmall volume at Edinburgh, of which they agreed to ſuperintend the publication, and defray the expence." Report of the Highland Society on the Poems of Oſſian, p. 27.

This ſmall volume contained the opening, and ſome epiſodes of Fingal; and an intimation was given, that if it were favourably received, the whole of Fingal might be recovered. A ſubſcription was accordingly ſet on foot, to enable Macpherſon to perform a tour through the Highlands to collect larger and more complete ſpecimens of Gaelic poetry. When he returned to Edinburgh, he communicated to his literary patrons the reſult of his expedition; and ſoon afterwards, Fingal, an epic poem in ſix books, was publiſhed, along with ſome ſmall detached pieces. In the year 1765, he publiſhed another epic poem, entitled "Temora." To one of the books of this poem, he annexed what he called the original Gaelic: but of the reſt he only publiſhed the tranſlations. At his death, however, he left 1000*l.* to defray the expence of the publication of the originals of the whole; on which publication we ſhall afterwards offer ſome remarks.

The ſucceſs which had attended Mr. Macpherſon's reſearches, and the fame which he had acquired by the publication of the poems of Oſſian, incited ſeveral others to proceed into the Highlands, and to collect from tradition or manuſcripts Gaelic ballads; while, as a ſuſpicion of the authenticity of what Macpherſon had publiſhed aroſe in the minds of many, enquiries were alſo ſet on foot, for the purpoſe, if poſſible, of detecting the ſuppoſed impoſture. There is reaſon to believe, too, that ſome of the poems, which were given to the world, after the ſucceſs and fame of Macpherſon, were not genuine Gaelic poems, nor even founded on the traditionary ballads of the Highlands, but entirely the fabrication of thoſe who publiſhed them.

In the year 1780, Mr. John Clark, land ſurveyor in Badenoch, publiſhed tranſlations of Gaelic poetry; the principal of theſe was a regular poem, in three books; two of which were afterwards publiſhed in a verſe tranſlation by Mrs. Grant of Laggan. In the ſame year, Mr. Hill, in a tour through the Highlands, collected, chiefly from one Macnab, a blackſmith in Argyleſhire, copies of ſeveral ancient poems: which from the incidents which they contain, and other internal evidence, muſt be deemed of a later date, than that which Macpherſon is diſpoſed to attribute to the poems which he publiſhed. Along with tranſlations of theſe poems Mr. Hill gave the Gaelic original; and to the whole he ſubjoined remarks, on the authenticity of Macpherſon's Oſſian, which at that time had become the ſubject of keen controverſy.

In the year 1786, a pretty large collection of Gaelic poetry of various dates was publiſhed at Perth: this volume contained ſeveral ſhort ballads, ſimilar in their ſubject to ſome of the poems publiſhed by Macpherſon.

But the moſt voluminous collector of Gaelic poetry, ſince the time of Macpherſon, was Dr. Smith, miniſter of Campletown in Argyleſhire. In the year 1780, he publiſhed Diſſertations on Gaelic antiquities, to which he annexed a collection of ancient poems, tranſlated from the Gaelic of Oſſian, Ullin, Oran, and others; and afterwards, in 1787, he publiſhed the originals. To his publication he ſubjoined an account of the manner in which he procured theſe originals.

In the year 1784, Dr. Young, afterwards biſhop of Clonmore, made an excurſion through the Scottiſh Highlands,

lands, for the purpoſe of collecting all the information in his power concerning the authenticity of Macpherſon's Oſſian. The reſult of his enquiries and inveſtigation he gave to the world in the firſt volume of the Tranſactions of the Royal Iriſh Academy. It conſiſted of ſome rude ancient Gaelic poems reſpecting the race of the Fions, which we have already had occaſion to notice and quote. Theſe poems Dr. Young tranſcribed letter for letter from the copies current in the Highlands, except ſo far as they were corrected by the edition publiſhed at Perth. Dr. Young does not mention the apparent antiquity of the MSS. from which he tranſcribed theſe ballads.

Theſe are the principal collections of Gaelic poetry which have been publiſhed, as preſerved by tradition or in manuſcripts, in the Highlands of Scotland. In Ireland a collection made its appearance ſoon after Macpherſon's Oſſian: this conſiſted of a tranſlation in rhyme, by Miſs Brooke, of ſome Iriſh ballads, which ſhe ſuppoſes to be of a later date than that in which Oſſian flouriſhed, and probably of the eighth, ninth, and tenth centuries. Moſt of theſe Iriſh poems relate to the Fingalians; but they differ both in the incidents which they relate, and in their manner and ſtyle, from the poems under ſimilar titles, which have been collected in the Highlands of Scotland. One moſt ſtriking difference conſiſts in the magical machinery of the Iriſh poems, inſtead of the mere reference to the belief of the employment and intervention of departed ſpirits, which the Fingalian poetry of the Highlands exhibits.

As the reſult of the reſearches of the Highland Society, which was given to the world in their report into the nature and authenticity of the poems of Oſſian, will fall more properly under our notice, when we come to diſcuſs that authenticity, we ſhall proceed to point out the moſt ſtriking characteriſtics of theſe poems.

On the firſt peruſal of theſe poems, the reader is ſtruck with their obſcurity; he finds it neceſſary to pauſe and reflect, before he can aſcertain the meaning of many paſſages, or perceive and trace the connection of the narrative. Even after he has become accuſtomed to the ſtyle, he is obliged to leave in deſpair many parts as abſolutely unintelligible, or at leaſt as conveying no clear and diſtinct idea or image to his mind; beſides this great fault, the poems labour under the imputation of being exceſſively bombaſtic and turgid; ſo that a reader of taſte and judgment has ſeveral difficulties to overcome, before he can ſit down to their peruſal, in ſuch a ſtate of mind and feeling, as will permit and enable him calmly and impartially to appreciate their merits. And even after he has got over the repugnance excited by their obſcurity and bombaſtic ſtyle, he will be in danger of being repelled and diſguſted by their ſentimental effuſions, which, in many inſtances, are of the moſt romantic and ſickly character. Still, however, there is ſomething in the poems which gets the better of all theſe objections; and which is more powerful in its attractions, than the faults which we have noticed are in their repulſive quality. The great characteriſtics of Oſſian's poetry, are undoubtedly, as Dr. Blair remarks, tenderneſs and ſublimity; but the tenderneſs is pathetic, melancholy, and ſolemn; and the ſublimity is dreary, deſolate, and gloomy. There is nothing gay or chearful; the mind of the reader is prepared for the grave and ſolemn events which they record, by the wild and romantic ſcenery which they deſcribe. "The extended heath by the ſea-ſhore; the mountain ſhaded with miſt; the torrent ruſhing through a ſolitary valley; the ſcattered oaks and the tombs of warriors overgrown with moſs;—all produce a ſolemn attention in the mind, and prepare it for great and extraordinary events."

The following paſſages may be cited as inſtances of the ſublime.

"As autumn's dark ſtorms pour from two echoing hills, ſo toward each other approached the heroes. As two dark ſtreams from high rocks meet and mix, and war on the plain: loud, rough, and dark in battle, met Lochlin and Inniſfail: chief mixed his ſtrokes with chief, and man with man. Steel clanging, ſounded on ſteel. Helmets are ceſt on high: blood burſts and ſmokes around. As the troubled noiſe of the ocean, when roll the waves on high; as the laſt peal of the thunder of heaven; ſuch is the noiſe of battle. The groans of the people ſpread over the hills. It was like the thunder of night, when the cloud burſts on Cona, and a thouſand ghoſts ſhriek at once on the hollow wind."

The ſublimity of the following paſſages is of a ſolemn and awful character:

"A dark red ſtream of fire comes down from the hill. Crugal ſate upon the beam: he that lately fell by the hand of Swaran, ſtriving in the battle of heroes. His face is like the beams of the ſetting moon. His robes are of the cloud of the hill. His eyes are like two decaying flames. Dark is the wound of his breaſt. The ſtars dim twinkled through his form; and his voice was like the ſound of a diſtant ſtream."

"Dim and in tears he ſtood, and ſtretched his pale hand over the hero; faintly he raiſed his feeble voice, like the gale of the reedy Lago. My ghoſt, O Connal! is on my native hills; but my corpſe is on the ſands of Ullin. Thou ſhalt never talk with Crugal, or find his lone ſteps in the heath. I am light as the blaſt of Cromla; and I move like the ſhadow of miſt. Connal, ſon of Colgar, I ſee the dark cloud of death. It hovers over the plains of Lena. The ſons of green Erin ſhall fall. Remove from the field of ghoſts. Like the darkened moon he retired, in the midſt of the whiſtling blaſt."

The following are inſtances of the other ſtriking characteriſtic of Oſſian's poetry, tenderneſs;—Gaul, the ſon of Morni, and the lover of Oithona, ignorant of the misfortune which had befallen her, comes to her reſcue, and propoſes to engage her foe in ſingle combat.

"And ſhall the daughter of Nuath live," ſhe replied with a burſting ſigh: "Shall I live in Tromathon, and the ſon of Morni low? My heart is not of that rock; nor my ſoul careleſs as that ſea, which lifts its blue waves to every wind, and rolls beneath the ſtorm. The blaſt which ſhall lay thee low, ſhall ſpread the branches of Oithona on earth. We ſhall wither together, ſon of car-borne Morni. The narrow houſe is pleaſant to me; and the grey ſtone of the dead; for never more will I leave theſe rocks, ſea-ſurrounded Tromathon. Chief of Struman, why cameſt thou over the waves to Nuath's mournful daughter? Why did I not paſs away in ſecret, like the flower of the rock, that lifts its fair head unſeen, and ſtrews its withered leaves on the blaſt? Why didſt thou come, O Gaul, to hear my departing ſigh? O had I dwelt at Davranna, in the bright beams of my fame. Then had my years come on with joy; and the virgins would bleſs my ſteps. But I fall in youth, ſon of Morni, and my father ſhall bluſh in his hall."

"No father mourned his ſon ſlain in youth; no brother, his brother in love; they fell without tears, for the chief of the people was low."

"And is the ſon of Semo fallen? ſaid Carril with a ſigh. Mournful are Tura's walls, and ſorrow dwells at Dunſcaich. Thy ſpouſe is left alone in her youth; the ſon of thy love is alone. He ſhall come to Brapla, and aſk her, why ſhe weeps. He ſhall lift his eyes to the wall; and ſee his father's

father's ſword. Whoſe ſword is that? he will ſay: and the ſoul of his mother is ſad."

The melancholy tenderneſs of Oſſian's poetry is alſo diſplayed in the following paſſage, in which the bard contraſts his preſent and his former ſtate.

"Such were the words of the bard in the days of the ſong; when the king heard the muſic of harps, and the tales of other times. The chiefs gathered from all their hills, and heard the lowly ſound. They praiſed the voice of Cona: the firſt among a thouſand bards. But age is now on my tongue, and my ſoul has failed. I hear ſometimes the ſhouts of bards, and learn their pleaſant ſong. But memory fails on my mind; I hear the call of years. They ſay, as they paſs along, why does Oſſian ſing? ſoon ſhall he lie in the narrow houſe, and no bard ſhall raiſe his fame. Roll on, ye dark brown years; for ye bring no joy in your courſe. Let the tomb open to Oſſian, for his ſtrength has failed. The ſons of the ſong are gone to reſt. My voice remains like a blaſt, that roars lonely on a ſea-ſurrounded rock, after the winds are laid. The dark moſs whiſtles there, and the diſtant mariner ſees the diſtant trees."

Beſides the ſublime and tender paſſages with which the poems of Oſſian abound, they are diſtinguiſhed by their ſtrong and lively deſcriptions, in which, often by a ſingle circumſtance, the picture is rendered moſt natural and impreſſive; the genius of the poet too lends to theſe deſcriptions all that intereſt, which pathetic reflection or tender feeling can beſtow; he ſeldom contents himſelf with the mere deſcription of natural ſcenery, without intermixing theſe peculiar traits of his diſpoſition and genius: this remark is moſt particularly exemplified in the following paſſage.

"I have ſeen the walls of Balclutha, but they were deſolate. The fire had reſounded within the halls; and the voice of the people is now heard no more. The ſtream of Clutha was removed from its place, by the fall of the walls; the thiſtle ſhook there its lonely head; the moſs whiſtled to the wind. The fox looked out of the window: the rank graſs waved round his head. Deſolate is the dwelling of Moina. Silence is in the houſe of her fathers."

We have room to particulariſe only one more of the excellencies of Oſſian's poetry; that is, the ſkill and effect with which he manages his ſimilies: the following is an inſtance.

"Wilt thou not liſten, ſon of the rock, to the ſong of Oſſian? My ſoul is full of other times; the joy of my youth returns. Thus the ſun appears in the weſt, after the ſteps of his brightneſs have moved behind a ſtorm. The green hills lift their dewy heads. The blue ſtreams rejoice in the vale. The aged hero comes forth on his ſtaff; and his grey hair glitters on the beam."

On the whole, the merits of Oſſian's poetry muſt be allowed to be great; it has alſo great faults: to thoſe whoſe judgment and taſte have been diſciplined by ſtudy, and formed on the models of antiquity, the faults will ſeem to counterbalance the beauties; but in the opinion of the multitude, the beauties will preponderate, and with them the poems of Oſſian will always be popular.

Almoſt as ſoon as the poems of Oſſian were given to the world by Macpherſon, doubts were raiſed concerning their authenticity; and theſe doubts were increaſed and ſtrengthened by the ſtrange and perverſe conduct of that gentleman: he pretended to have collected manuſcripts in the Highlands, from which he had tranſlated theſe poems; to have theſe manuſcripts, of undoubted antiquity as he maintained, in his poſſeſſion; and yet, when the poems were branded as forgeries, inſtead of ſilencing the ſceptics and accuſers by the production of theſe manuſcripts, he maintained a ſullen and obdurate ſilence. Beſides the unwillingneſs or inability of Macpherſon to produce the manuſcripts which he aſſerted he had diſcovered in the Highlands, or to name the perſons from whom he had received them, there were other ſuſpicious circumſtances affixed to theſe poems. The literati of England, and in an eſpecial manner Dr. Johnſon, pronounced them forgeries; and the latter was confirmed in his opinion (if confirmation he needed) when, in his journey through the Highlands, he could collect only very vague, general, but moſt peremptory and poſitive aſſertions, that the poems publiſhed by Macpherſon were authentic, and had been well known there for generations. The controverſy concerning their authencity, however, did not proceed to any length, or aſſume any regular and methodical form till the year 1800, when Mr. Malcolm Laing publiſhed his Hiſtory of Scotland; to the ſecond volume of this hiſtory he annexed a learned, moſt acute, and ingenious diſſertation on Oſſian's poems. In any controverſy which had been agitated on this ſubject, before Mr. Laing took it up, the whole jet of the argument and proof lay on the exiſtence, in tradition or manuſcript, of poems in the Highlands, compoſed by Oſſian, and ſimilar in all their leading features to thoſe publiſhed by Macpherſon: the internal evidence, though generally mentioned by the diſbelievers in their authenticity as ſtrongly in favour of their opinion, was never minutely and thoroughly examined, before Mr. Laing inveſtigated it. The objections to the authenticity of theſe poems may be thus ſtated and arranged.

1. It is highly improbable, that at the time when Oſſian lived, he could compoſe ſuch long and regular poems, without the uſe and aſſiſtance of letters; and the moſt ſturdy and zealous advocates for theſe poems, will not contend that letters were known in the Highlands in the third century. It may indeed be urged, that Homer compoſed his Iliad and Odyſſey, when he was equally a ſtranger with Oſſian to the uſe of letters; but of this aſſertion there is no proof; the preſumption on the contrary is, that in the time of Homer, letters were known in Greece. It is ſcarcely neceſſary to dwell on the poſition here laid down, that if letters were unknown in the Highlands in the time of Oſſian, that bard's compoſitions muſt have been very ſhort, and probably very irregular; certainly not of the deſcription of poems which Macpherſon publiſhed in his name, and which Dr. Blair, in his Diſſertation, has proved to be written in exact conformity to the rules which Ariſtotle lays down for the compoſition of an epic poem.

2. Even allowing that ſuch long and regular poems could have been compoſed without the uſe of letters; it is not credible, that they could have been tranſmitted from the time of Oſſian to the time of Macpherſon, or at leaſt to the time of the date of the moſt ancient manuſcripts found in the Highlands. This objection cannot be put in a ſtronger way, than in the words in which Hume has expreſſed it, in a letter to Gibbon. "It is indeed ſtrange, that any man of ſenſe could have imagined it poſſible, that above 20,000 verſes, along with numberleſs hiſtorical facts, could have been preſerved by oral tradition, during fifty generations, by the rudeſt, perhaps, of all civilized nations, the moſt neceſſitous, the moſt turbulent, and the moſt unſettled." There is nothing ſimilar to this in any other language, or among any other nation: the Gothic poems are all ſhort; the death ſong of Radnor Lodbrog, which is amongſt the longeſt pieces of Gothic poetry, ſuppoſed to be traditionally preſerved, extends but to twenty-nine octavo ſtanzas, of ſhort lines; and in order to relieve the memory in this and other Gothic poems, there is always a burden. Beſides, theſe ballads

ballads were written only a few centuries before letters were common among the Gothic nations; and conſequently, their preſervation (independently of the circumſtance of their ſhortneſs) cannot be conſidered as in the leaſt ſimilar to the ſuppoſed preſervation of Oſſian's poems.

When Macpherſon firſt publiſhed his fragments in 1760, in order to prove their antiquity, he aſſerts, that "the diction is very obſolete, and differs widely from the ſtyle of ſuch poems, as have been written in the ſame language two or three centuries ago;" and the Highland Society, in their Report, make uſe of a ſimilar argument: "no modern could poſſibly write ſuch Gaelic as the original given by Macpherſon, in his Temora, any more than the beſt Greek or Latin ſcholars could write what would paſs itſelf, on perſons converſant in thoſe languages, for the compoſition of Homer or Virgil;" and yet, in the ſame Report, it is ſtated, that the language in theſe poems is nearly what it ſtill is in the common uſe and underſtanding of the country. Theſe aſſertions evidently contradict one another; but let the believers in the authenticity of Oſſian's poems chooſe which they pleaſe, it will equally militate againſt their belief. If the Gaelic of Oſſian's poems, as publiſhed by Macpherſon, is the Gaelic in the common uſe and underſtanding of the country at this day, then it is Gaelic, which might have been written by him; and the poems might have been forged by him; and the argument for their authenticity falls utterly to the ground: if, on the other hand, the Gaelic of theſe poems is ſuch as no modern could poſſibly write, then they could not have been tranſmitted, either in manuſcript or tradition; for, as Mr. Laing obſerves, "that the poems were preſerved by oral tradition, in an obſolete diction, or, in other words, a dialect already diſuſed by the people, is alone ſufficient to confute their authenticity." If the poems are ſtill current and popular in the Highlands, they muſt be underſtood; if underſtood, they muſt be written in a language familiar and ſimilar to modern Gaelic; and if written in this language, they might have been forged.

3. The poems of Oſſian, as publiſhed by Macpherſon, are very diſſimilar, in their ſentiments and character, from other poems written in the ſame ſtate of ſociety. Dr. Blair, in his Critical Diſſertation, after quoting the funeral ſong of Radnor Lodbrog (already referred to) obſerves, "this is ſuch poetry as we might expect from a barbarous nation; it breathes a moſt ferocious ſpirit. It is wild, harſh, and irregular; but at the ſame time animated and ſtrong: the ſtyle in the original, full of inverſions, and as we learn from ſome of Olaus' notes, highly metaphorical and figured. But when we open the works of Oſſian, a very different ſcene preſents itſelf. When we turn from the poetry of Lodbrog to that of Oſſian, it is like paſſing from a ſavage deſert to a fertile and cultivated country." It might have been ſuppoſed, that the utter diſſimilarity between the poetry of Oſſian, and that of the Gothic nations, at nearly the ſame era, would have excited ſuſpicions in the mind of Blair, reſpecting the authenticity of the former; inſtead of that, he enters into a learned diſquiſition to prove, that the Celtic nations were much more refined and civilized than the Goths; and that this ſuperior refinement and civilization were owing to the eſtabliſhment of the Druids among them. Let us grant, for a moment, that the Celtic nations were thus diſtinguiſhed above the Goths; ſtill this will not account for the character of Oſſian's poetry; no ſtate of ſociety, but that in which very refined and ſubtle feelings are indulged, in which what may be ſtyled the luxury of ſentiment is known, could have produced ſuch poems as thoſe which were publiſhed by Macpherſon. The Celts, if they were farther advanced in knowledge and civilization than the Goths, might have produced poetry free, in a great meaſure, from that ferocious ſpirit, and from that wildneſs, harſhneſs, and irregularity, which Blair notices in the death ſong of Radnor Lodbrog; but it would ſtill have retained many of the marks of a barbarous age. But the poetry of Oſſian, as publiſhed by Macpherſon, is not only unlike that of the Goths, but it is as unlike that Gaelic poetry, which is known to be genuine. The latter, as given to the world by Dr. Young, the Highland Society, &c. agrees in every reſpect with the idea which has always been entertained of the poetry of a rude people; the ſtyle of it is very unequal; "ſometimes tame and flat; ſometimes turgid and highly periphraſtic: ſometimes it riſes into ſavage energy, and ſometimes melts into natural tenderneſs." The manners exhibited in this genuine Gaelic poetry, alſo, are ſuch as might be expected in a ſavage nation: in one of the poems given in the appendix to the Report of the Highland Society, Fingal knocks Carril on the head for diſputing with him the property of a beef ſtake, dreſſed with onion ſauce. Unleſs, therefore, we can bring ourſelves to believe, that in the third or fourth century the Highlanders were ſuperior in knowledge, refinement, and delicacy of feeling and ſentiment, not only to their Gothic contemporaries, but even to moſt European nations at the preſent time; and that they afterwards became ſavage and unenlightened, we muſt doubt the authenticity of Oſſian's poems.

4. The omiſſion of religion, and of all ſpecific and circumſtantial notice of the manners and cuſtoms of the age, is a ſtrong preſumption againſt their authenticity. Macpherſon was ignorant of the gods and rites of the Caledonians: according to his hiſtorical theory, the Druids had been expelled by the Fingalians; and it was not therefore to be ſuppoſed, that the latter would adopt the religion of the former: he had, therefore, no other alternative but to fill his poems with ghoſts; in which there is no proof that the Celts believed, and which are not to be traced in any of the authentic Gaelic ballads. There is no ſource more ample and more accurate, from which the manners, cuſtoms, and mode of life of ancient nations can be drawn, than from their ballads: but on theſe points Oſſian's poems preſerve a guarded and ſuſpicious ſilence. In the time of Macpherſon's heroes, hunting was the principal amuſement; and yet the wild cattle, the wolves, and the boars, are never mentioned.

5. The inconſiſtency of the events related in theſe poems, with the Roman hiſtory of Britain, and with the hiſtory of the middle ages, has been very able pointed out by Mr. Laing as one proof of their forgery. "The arrival or return of the Scots from Ireland, under Fergus Mac Erth, and his brother Loarn, is eſtabliſhed by the concurrence of every Scottiſh and Iriſh hiſtorian; and their firſt arrival is marked by Bede, under Riada their leader, from whom their ſettlement was named Dalriada:" hence it is an hiſtorical fact that there was not a Highlander in Scotland of the preſent race, at the beginning of the era aſſigned to Fingal. This obſervation will derive great additional weight, if we have proved that Fingal and his heroes belong originally to Ireland, and conſequently, were probably introduced to the knowledge of the Highlanders, at the era of the Dalriadic ſettlement in Scotland. Fingal, in the poems publiſhed by Macpherſon, is connected with Caracalla in 208, and with Carauſius in 286; and his reign and exploits are prolonged in the Temora to the battle of Gabhra in 296; "with the ſame propriety (Mr. Laing obſerves), as if a youthful patriot, who reſiſted a union in the Scotch parliament, were again introduced at the end of the century, oppoſing a union with Ireland, in the Britiſh ſenate." Caracalla, the ſon of Severus (to uſe the words of Gibbon) "is

deſcribed by a nick-name invented four years afterwards, ſcarcely uſed by the Romans till after the death of that emperor, and ſeldom employed by the moſt ancient hiſtorians:" an awkward and unſatisfactory attempt has been made to get rid of this objection, by obſerving that Caracul, in Gaelic, means fierce-eyed. The Roman province of Valentia, into which Fingal is repreſented as having made an incurſion, did not then exiſt; and Dumbarton, which is mentioned in the poems, was not then built; Lochlin was certainly unknown in the third century, notwithſtanding Dr. Graham, in his reply to the objections of Mr. Laing, controverts this poſition, on the very doubtful authority of a MS. deſcribed by Dr. Donald Smith; and Orkney, in which Inniſtere is placed, if credit is given to the preciſe aſſertion of Solinus, rather than to the rhetorical period of Tacitus, was then uninhabited. It is unneceſſary to go through the hiſtorical detections drawn from the middle ages; they are equally numerous and deciſive; and are given with great acuteneſs and learning by Mr. Laing.

6. In oppoſition to theſe ſtrong preſumptions againſt the authenticity of Oſſian's poems, and to the internal evidence of their modern date, it would require the moſt unequivocal and full proof, that they had been actually collected by Macpherſon from tradition, or copied from ancient manuſcripts, in order to ſilence ſcepticiſm. But this proof is miſerably deficient, and, according to the acute obſervation of Mr. Laing "negative evidence with reſpect to the authenticity, becomes poſitive evidence with reſpect to the forgery of the poems." It appears from various letters publiſhed in the Report of the Highland Society, that Macpherſon, during his tour through the Highlands, viſited ſeveral people who were ſaid to poſſeſs MSS., or who were converſant in Gaelic poetry; that he aſſerted he had been very ſucceſsful in the purſuit of his object; and that to ſeveral he ſhewed ſome of the MSS. which he had procured, and from them tranſlated paſſages, which are ſtated to have been ſimilar to what he afterwards publiſhed. But this teſtimony is very vague and unſatisfactory: the ſpecific paſſages are not pointed out; the MSS. which Macpherſon ſhewed were not examined. In ſhort, the teſtimony afforded by theſe letters, is exactly of that ſort againſt which Dr. Johnſon proteſted: he found in the Highlands, many who maintained, that they were perfectly acquainted with Oſſian's poems before the time of Macpherſon; but he could get no direct and explicit anſwer, when he aſked which of the poems, or requeſted them to point out exactly the paſſages with which they had been previouſly acquainted.

With reſpect to the MSS. ſaid to have been procured by Macpherſon, he always refuſed to produce them, except one, which Mr. Laing examined, and which, inſtead of being a MS. of Oſſian's poems, is an Iriſh MS. in a character and language, which ſcarcely any Highlander can diſtinctly read; and which, as far as it has been made out, contains no poems either of Oſſian, or of any other bard. It has been already mentioned, that Macpherſon left a ſum of money for the purpoſe of publiſhing his Gaelic MSS. after his death; from ſome cauſe or other, their publication was delayed till the year 1807, when they appeared with a literal tranſlation into Latin, by the late Robert Macpherſon, A.M., together with a diſſertation on the authenticity of the poems, by ſir John Sinclair; a tranſlation on the abbé Ceſarotti's Diſſertation on the Controverſy, with notes, and a ſupplemental eſſay, by Dr. Mac Arthur; the work was publiſhed under the ſanction of the Highland Society of London. The editors of this work thought that they ſhould decide the controverſy; but there were certain awkward and troubleſome queſtions aſked: the Gaelic poems thus publiſhed, were all in Macpherſon's hand-writing; what had become of the MSS. which he pretended to have got in the Highlands, and from which, if they really exiſted, he muſt have made his copy? To this no ſatisfactory anſwer can be given. On the margin of the firſt edition of his Oſſian, Macpherſon marked, with his own hand, the time when the Gaelic was delivered to Mr. John Mackenzie, the ſecretary to the Highland Society; among theſe memoranda, the following are found, "delivered the three Duans of Cathlode, as *complete as the tranſlation.*" Does not this expreſſion warrant the belief that the Gaelic was written after the Engliſh; elſe why ſay, as complete as the tranſlation? It would be natural and proper to talk of a tranſlation being as complete as the original; but to ſpeak of an original being as complete as the tranſlation, would ſcarcely have occurred to any one, whoſe thoughts and language had not been at direct variance. Again, he ſays, "delivered all that could be found of Carthon;" but, if the Engliſh Carthon had been the tranſlation, why could he find little more than half the original from which the tranſlation was made? The mere circumſtance of the poems of Oſſian being publiſhed in Gaelic, from MSS. in Macpherſon's hand-writing, can prove nothing in favour of their authenticity; nor be a ſatisfactory anſwer to thoſe who called for MSS., before they would give up their ſcepticiſm; unleſs there had been ſatisfactory evidence, that this Gaelic Oſſian had been copied from old MSS; for Macpherſon could forge poems, as well in Gaelic as in Engliſh; and the undoubted facts, that he never would ſhew any old MSS; that he delayed publiſhing the Gaelic during his life-time, and that he was very ſlow in delivering it over to thoſe to whom he committed the publication, confirm the ſuſpicion of Mr. Laing, that he *tranſlated* his Engliſh Oſſian into Gaelic, and that this tranſlation he left for publication after his deceaſe.

7. Macpherſon publiſhed a poem called the Highlander, before he appeared as the tranſlator of Oſſian's poems: the ſimilarity between the Highlander and Oſſian in deſcription, ſentiment, manner, and ſtyle, is uncommonly ſtriking and cloſe; indeed Mr. Laing has proved that many paſſages of the former were tranſcribed by Macpherſon into his Oſſian. In a work publiſhed by Mr. Laing ſubſequently to his Diſſertation, he has detected in the poems of Oſſian many palpable and groſs plagiariſms from Homer, Virgil, and their two tranſlators; Milton, Thomſon, Young, Gray, Maſon, Home, and the Engliſh bible. Several of the inſtances given by Mr. Laing are undoubtedly ſtrained, and would never have been brought forward as proofs of plagiariſm, by a mind not warmed by a generous indignation againſt impoſture; but moſt of them are of ſuch a nature, as can leave no doubt that Macpherſon, in the compoſition of Oſſian's poems, either copied the authors we have mentioned, or was ſo fully imbued with their ſpirit, that even his own thoughts and expreſſions aſſumed the ſhape of theirs.

8. Macpherſon, in various paſſages of his prefaces and introductions, ſeems diſpoſed to acknowledge the impoſture, and to claim the higher merit of an original poet: in one place he ſays, "Thoſe who alone are capable of transferring ancient poetry into a modern language, might be better employed in giving originals of their own, were it not for that wretched envy and meanneſs, which affects to deſpiſe contemporary genius. I aſſure my antagoniſts, I ſhould not tranſlate what I could not imitate:" and in his preface he ſays, "without *increaſing* his genius, the *author* may have improved his language, in the eleven years that the poems have been in the hands of the public." And again, "in a convenient indifference for a literary reputation, the author hears praiſe without being elevated, and ribaldry without

out being depreſſed:" and in the concluſion he ſays, "the tranſlator, *who cannot equal his original*, is incapable of expreſſing its beauties." Theſe paſſages, if taken by themſelves, would perhaps prove but little; but when conſidered in connection with all the other ſuſpicious circumſtances; with Macpherſon's inability to produce any ancient MSS.; with the plagiariſms contained in the poems; and with the internal marks of forgery which they diſplay; they tell ſtrongly againſt their authenticity. But there is more direct and poſitive proof that Macpherſon confeſſed the impoſture: the late venerable biſhop of Dromore, in a letter to a friend (quoted by the Britiſh Critic, for 1809, p. 275.) ſays, "I repeatedly received the moſt poſitive aſſurances from ſir John Elliot, the confidential friend of Macpherſon, that all the poems, publiſhed by him, as tranſlations of Oſſian, were entirely of his own compoſition. This I did not underſtand ſo ſtrictly as that Macpherſon might not have introduced ſome fragments of ancient Erſe poetry, preſerved by tradition; but that he had no genuine originals of Oſſian's compoſition. This, ſir John Elliot did not communicate to me as the reſult of one ſingle converſation, but what he was fully aſſured of, by repeated converſations, during the intimacy of many years."

9. In the year 1797, the Highland Society of Edinburgh appointed a committee to enquire into the nature and authenticity of the poems of Oſſian. By the direction of this committee, queries very diſtinctly and accurately worded, were tranſmitted to every one, who from perſonal knowledge, or opportunities of enquiry, was ſuppoſed capable of throwing light on the ſubject. In 1805, the report of this committee was publiſhed, ſanctioned by the name of Mr. Henry Mackenzie, chairman. The line of conduct purſued by the committee was very ſimilar to that which had been chalked out by Hume, in a letter to Blair, ſoon after the firſt appearance of the poems of Oſſian by Macpherſon. Dr. Blair had written to Hume reſpecting the reception in England, of his diſſertation on theſe poems: Mr. Hume, in his anſwer, mentions the general incredulity of the Engliſh literati on their authenticity, ariſing partly from the behaviour of Macpherſon, who refuſed to ſatisfy any one who doubted of his veracity, and partly from the extreme improbability that ſuch long connected pieces ſhould have been preſerved by oral tradition for fourteen centuries. Mr. Hume there points out the line of conduct which it would be neceſſary for Dr. Blair to purſue, if he wiſhed to ſilence this general ſcepticiſm: "the teſtimonies may, in my opinion, be of two kinds. Macpherſon pretends that there is an ancient MS. of part of Fingal in the family, I think, of Clanranold; get that fact aſcertained by more than one perſon of credit: let theſe perſons be acquainted with the Gaelic: let them compare the original and the tranſlation; and let them teſtify the fidelity of the latter. But the chief point in which it will be neceſſary for you to exert yourſelf will be, to get poſitive teſtimony from many different hands, that ſuch poems are vulgarly recited in the Highlands, and have there been long the entertainment of the people. This teſtimony muſt be as particular as it is poſitive. It will not be ſufficient that a Highland gentleman or clergyman ſay, or write to you that he has heard ſuch poems: nobody queſtions that there are traditional poems in that part of the country, where the names of Oſſian and Fingal, and Oſcar and Gaul, are mentioned in every ſtanza. The only doubt is, whether any of theſe poems have any farther reſemblance to the poems publiſhed by Macpherſon. Generality muſt be carefully guarded againſt, as being of no authority."

It is evident from theſe precautionary directions that Mr. Hume was well aware of the looſe and unſatisfactory evidence which moſt probably would be produced in ſupport of the authenticity of Oſſian; and the Highland Society, notwithſtanding they tranſmitted very clear, preciſe, and diſtinct queries, received, in moſt caſes, only very general anſwers: ſuch was the impatient zeal, or ſuch the clouded underſtandings of the Highlanders on this ſubject, that they either would not permit themſelves to reply to any objections with an appeal to facts, or they miſapprehended the queſtion, and ſuppoſed it was the exiſtence of traditionary poetry reſpecting Oſſian and Fingal, and not the fidelity of Macpherſon's tranſlation, on which they were requeſted to give evidence. The conſequence was, that much of the evidence produced on the report of the Highland Society, is quite exceptionable, on the grounds which Hume ſtates and wiſhes to guard Dr. Blair againſt; and the evidence which goes to the point, only confirms that ſcepticiſm which it was intended to remove; ſince it only proves that there were in the Highlands MSS. and traditionary ballads, reſpecting Fingal and his heroes, attributed to Oſſian, of which ballads Macpherſon had made uſe, but which were *not* the originals of his poems.

In the report it is expreſsly admitted, "that the committee has not been able to obtain any one poem the ſame in title and tenor with the poems publiſhed by Macpherſon." This admiſſion is ſufficient to put the ſeal upon the queſtion of their forgery. The Highland Society, after this admiſſion, ſhould have diſdained the unworthy and ridiculous ſubſtitute to which they have had recourſe in order to *make out* ſomething like an original for ſome of Macpherſon's poems. The language of Mr. Laing in the following paragraph, though ſtern and harſh, is but too applicable to this diſingenuous expedient.

"Inſtead of complying with this plain and pointed requiſition, the committee of the Highland Society employed the late Dr. Smith to collect ſuch paſſages from theſe MSS. as might bear or acquire a remote affinity to Macpherſon's Fingal. For this purpoſe thirteen or fourteen modern MSS. were taken, containing many hundred pages, and conſiſting of different collections of Erſe and Iriſh poems. From this extenſive range, between twelve and fifteen hundred detached lines are ſelected, and pieced together with the moſt prepoſterous diligence, in order to preſent to the reader, by dint of tranſlation, ſomething like the plan and outlines of Fingal. No intimation is given of the particular ſongs or poems from which they are taken; but the references to the different pages are as deſultory as the lines themſelves are unconnected and detached." Mr. Laing then gives ſome ſpecimens of this mode of piecing poetry together; and concludes with this remark: "This, if practiſed in any other language than Erſe, would be deemed fabrication." This patch-work poetry has been happily likened to the expedient of brother Martin, in the Tale of a Tub, to diſcover authority in his father's will for wearing ſhoulder-knots: as they were not expreſsly mentioned, he ſought them firſt, *totidem verbis*, then *totidem ſyllabis;* and at laſt, all failing, *totidem literis*.

There can be no doubt that Macpherſon collected Gaelic poetry, and made uſe of it in his Oſſian; but his materials were few and ſcanty, and of a very different character, in every reſpect, from the poems which he conſtructed from them. Fingal is principally founded on a ballad narrating the invaſion of Ireland, by Magnus the Bare-footed: this ballad contains about fifty ſtanzas of four lines each; which Macpherſon has enlarged into ſix books, and thrown into the form of a regular epic poem. The ſtory of the ballad bears ſome reſemblance to that of Fingal; but in the former there

there is no mention of the battle between Cuthullin and Sivaran, nor of thoſe circumſtances related by Macpherſon in ſuch detail, and by means of which he has ſwelled Fingal into ſix books. Beſides this ballad of Magnus, Macpherſon, in the compoſition of his Fingal, has made uſe of other ſmall genuine pieces of Celtic poetry.

The battle of Lora, the next piece for which any authority has been diſcovered, is founded on a poem called Erragon: the incidents are nearly the ſame, but the manner of relating them, the ſentiments and the language, are extremely unlike; and theſe ſufficiently prove, that the peculiarities of Oſſian's poetry are, in fact, the offspring ſolely of Macpherſon's muſe.

Carthon, the next poem, is founded on the tale of Conloch, natural ſon of Cuchullin, who being educated in Scotland, comes to Ireland, encounters his father there, without being known to him, and is ſlain by him. Macpherſon has altered the incidents in ſome reſpects; and as uſual, ſubſtituted his own ſentiments and language. There is good reaſon for ſuppoſing that the famous addreſs to the ſun, with which this poem concludes, is not genuine. No Gaelic original has been diſcovered for the death of Cuthullin. Darthula is well known in the Highlands under the name of *Devidre;* but Macpherſon has very materially altered the ſtory. The ballad of Lammon Mor ſeems to have been the foundation of Macpherſon's "Luthmon;" but in the latter the ſtory is told differently; and the night attack by Oſſian and Gaul, with the imagery which Blair extols, are not in the ballad. For the firſt book of Temora there is ſome authority, in a poem celebrating the fatal battle of Gabhra, in which Oſgur and moſt of the Fions were ſlain: as, however, Macpherſon intended, when he publiſhed the firſt book of Temora, to add a ſecond, he has omitted this cataſtrophe; and the Fions ſtill live and fight. Such are the ſlender materials on which Macpherſon conſtructed the pieces contained in his firſt publication: for thoſe contained in his ſecond volume, no genuine authorities can be found.

The reſult, therefore, of the enquiries of the Highland Society, muſt be conſidered as having finally and completely ſettled the queſtion reſpecting the authenticity of Oſſian's poems. As publiſhed by Macpherſon, they are much more his own, even in incidents, and moſt eſpecially, in ſentiment, imagery, and language, than the compoſition of Oſſian or any Celtic bard; and the ballads which he employed in their conſtruction, or ſuch as exiſt in MS. or in tradition in the Highlands, can on no poſitive or probable evidence be aſcribed to Oſſian; nor indeed traced up to any particular bard or era.

If further information is wanted on this ſubject, the following works may be conſulted; "Laing's Diſſertation on Oſſian's Poems," annexed to the ſecond volume of his Hiſtory of Scotland. "The Poems of Oſſian, &c. containing the poetical works of James Macpherſon, eſq. in proſe and rhyme, with notes and illuſtrations;" by the ſame author. "Report of the Committee of the Highland Society of Scotland, appointed to enquire into the nature and authenticity of the Poems of Oſſian, drawn up according to the directions of the Committee by Henry Mackenzie, eſq. with a copious appendix, containing ſome of the principal documents on which the account is founded." "The Poems of Oſſian in the original Gaelic, with a literal tranſlation in Latin, by the late Robert Macpherſon, A.M., together with a diſſertation on the authenticity of the Poems, by ſir John Sinclair, bart. &c. publiſhed under the ſanction of the Highland Society of London." And "Eſſays on the Authenticity of the Poems of Oſſian, in which the objections of Malcolm Laing, eſq. are particularly conſidered and refuted by Patrick Graham, D.D." &c.

Some forty years ago, meeting Mr. Macpherſon at the earl of Eglinton's, who prevailed on him to ſing two or three airs that he had learned of his mother, who knew neither Engliſh nor muſic: but in the ſame manner as our villagers keep alive the babes in the wood, and chevy chace, by tradition, ſhe ſung, in the Erſe language, melodies to words of Oſſian, which her ſon had tranſlated and adapted to the meaſures and melodies of his mother's ſinging. The French, the Italians, and the Germans, having no doubts of the authenticity of the poems of Fingal and Oſſian, were extremely ſtruck with the bold wildneſs and original ideas of theſe poems, and when at Hamburgh, we mentioned, in the company of the Milton of Germany, Klopſtock, the being in poſſeſſion of the following melodies, which we wrote down for the firſt time perhaps that they were ever received on paper, he moſt earneſtly intreated us to favour him with tranſcripts of theſe airs, which we readily promiſed to do: but, to our great regret, we were never able to find them till two or three months after his deceaſe. We therefore now give them a place on our plates, not only as curioſities, but to appeaſe the manes of the ſublime Klopſtock. For the airs, ſee *Plate Muſic* XLV.

OSSICULA AUDITUS, in *Anatomy*, the three ſmall bones contained in the cavity of the tympanum. See EAR.

OSSICULA *Muſculorum*, in *Ichthyology*, a name given by authors to thoſe oblong and ſlender bones which are ſituated in the fleſh of ſome kinds of fiſh between the muſcles: theſe, in the anterior part, and eſpecially near the head, are of a forked ſhape; but in the hinder part of the body, they are uſually ſimple and ſlender. Theſe ſorts of bones are found in the following kinds of fiſh: 1. In all the cyprini. 2. In the eſoces. 3. In the clupeæ. 4. In the eels. 5. In the coregones. 6. In the oſmerus. 7. In the ſalmon kind. 8. In mackrel. And 9. In the ammodytes or ſand-eel. In the five laſt, theſe bones touch the ſpine at one end, but in the others they no where come near it.

The uſe of theſe looſe bones ſeems to be, to ſtrengthen and ſupport the muſcles, that by this means they may be able the more forcibly to move the body, and turn it about: they are peculiar to fiſh, no land animal having them.

OSSIFICATION, in *Anatomy*, the converſion into bone, as, for example, of a cartilage, in the natural proceſs of formation of the ſkeleton; or of any other texture, in diſeaſed changes of its nature. This proceſs is deſcribed under BONE.

OSSIFRAGUM, in *Botany*, a name given by Bartholine, and ſome other writers, to a peculiar kind of graſs, growing in ſome parts of Norway. It comes up early in the ſpring, before any other graſs, and the cattle are tempted to eat it: but it emaciates them, and makes them ſickly; their back bones become protuberant if they feed any time on it, and their legs ſo weak that they can hardly go. The remedy among the country people is a very bad one. They collect the bones of different animals, and break them into ſmall pieces. The cattle greedily devour this ſort of food when offered them in this diſeaſe, and there follows a ſort of drivelling at the mouth for a conſiderable time, after which they become well. It is poſſible there may be much error in this ſtory. The kingdom of Norway is full of mines, and the effluvia of theſe may be the occaſion of the cattle's illneſs, and the ceaſing of theſe effluvia their cure; for it is not probable that either of theſe effects ſhould be owing to the graſs or the bones.

OSSIG, in *Geography*, a town of Sileſia, in the principality

pality of Neiſſe; three miles N.E. of Grotkau.—Alſo, a town of Saxony, in the biſhopric of Naumburg; four miles S. of Zeitz.

OSSIPAGINA, in *Botany*, a name given by Arnobius and ſome other of the old Greek writers to the *conſolida major*, or greater comfry. It had this name from its ſuppoſed quality of agglutinating broken bones on being taken internally.

The Greek writers have ſometimes called this plant *pectè*.

OSSIPEE, Ossapee, or *Oſapy*, in *Geography*, a poſt-town, mountain, and pond, in Stratford county, New Hampſhire, North America. The town was incorporated in 1785, and has 804 inhabitants. The lake lies N.E. of Winnipiſçogee lake, between which and Oſſapee lake is Oſſapee mountain. Its waters run E. and are joined by South river, from Great Oſſapee river, which diſcharges itſelf into Saco river, near the diviſion line between York and Cumberland counties in Maine, and between Limerick and Gorham.

OSSNOBIAN, Asseneboyne, *Indians*, a tribe found about the ſource of Oſſnobian or Aſſeneboyne river, far W. of lake Superior. The Moravian miſſionaries report, that they live wholly upon animal food, or that they reſtrict themſelves to the ſpontaneous productions of nature, denominating thoſe who dig the ground "ſlaves." Bread is unknown to them; and they reject it from their mouths, calling it rotten wood. Theſe Indians, as well as thoſe numerous nations who inhabit the country from lake Superior towards the Shining mountains, are great admirers of the beſt hunting horſes, with which the country abounds. The Oſſnobians have no permanent place of abode, and live wholly in tents made of buffalo and other hides, with which they travel from one place to another, like the Arabs: and as ſoon as the food for their horſes is expended, they remove, and pitch their tents in another fertile ſpot, and thus they emigrate, without ſcarcely ever returning to the ſame ſpots again.

OSSOLA, or Oscella, a diſtrict of Italy, between the Valais and lake Maggiora, about 35 miles in length and from 15 to 25 in breadth,; the country is compoſed of mountains and vallies, but is fertile and populous. The capital is Domo d'Oſcello.

OSSOLIN, a town of Poland, in the palatinate of Sandomirz; 20 miles W. of Sandomirz.

OSSOORAH, a town of Hindooſtan, in Bengal; 16 miles N. of Biſſunpour.

OSSORY, the name of a biſhopric in Ireland, the cathedral of which is at Kilkenny. It includes almoſt the whole county of Kilkenny, a good part of the Queen's county, and ſome of the King's county, extending 46 Engliſh miles in length and 29 Engliſh in breadth, and containing 136 pariſhes. Such, however, are the unions, that there are only 56 benefices, and of theſe 20 were without churches when Dr. Beaufort publiſhed. There is alſo a barony called Oſſory, which gave the title of earl to the eldeſt ſon of the dukes of Ormond.

OSSUN, a town of France, in the department of the Upper Pyrenées, and chief place of a canton, in the diſtrict of Tarbes; ſix miles S.S.W. of Tarbes. The place contains 1200, and the canton 10,558 inhabitants, on a territory of 160 kiliometres, in 15 communes.

OSSUNA, an ancient and well-peopled town of Spain, in the province of Seville. It derives great advantage in caſe of a ſiege, from a fountain in the middle of it, which furniſhes water to the inhabitants, whilſt the whole country, for eight miles round, is totally deſtitute of that neceſſary article. When Cæſar beſieged Oſſuna, he was obliged to bring his proviſions, and particularly water, from a great diſtance; 45 miles miles N.E. of Seville.

OST, in *Rural Economy*, a term applied to the kiln for drying hops. See Kiln, and Oost.

OSTADE, Adrian Van, in *Biography*, one of the very firſt claſs among the Flemiſh painters, was born at Lubeck in 1610, and was a diſciple of Frank Hals, in company with Brouwer, with whom he contracted a cloſe intimacy.

The choice of Oſtade in the ſubjects he repreſented is ſomewhat ſimilar to that of Teniers, but he treated them in a manner totally diſtinct, though not with ſo lively and ſpirited a touch, or ſo light and clear a management of his materials; yet with more care, more truth, and fullneſs of nature in the effects of colour and of chiaro-ſcuro, and with a great deal more meaning in the actions and expreſſions of his figures. Theſe it muſt be confeſſed are generally of the loweſt claſs, vulgar and groſs in form, and in habits; and placed where uſually ſuch objects are to be found, in dirty hovels: yet among ſuch animals little better than brutes, engaged in actions of groſs gratification, ſuch is the power of his pencil, ſo agreeable are the hues he employs, and the arrangement of light and ſhade in which they are diſpoſed, that the moſt refined eye dwells upon his pictures with delight. He ſurpriſes our judgment into implicit admiration, by a truth of character, and energy of effect, which precludes the foundation of cenſure.

It is true his pictures are not always of ſuch low ſubjects, but he never riſes to any thing like gentility in character, and very ſeldom attempted it. His works are too highly laboured to be very numerous, and are, therefore, to be bought only at high prices. He was ſo much eſteemed by contemporary artiſts, that many of the moſt eminent ſolicited him to put the figures in their landſcapes, which by that means received an additional value. Oſtade died in 1685, at the age of 75.

His younger brother, Iſaac Van Oſtade, was taught by him the art of painting, and imitated the ſtyle and taſte of his inſtructor; but he died young, and never arrived at any degree of ſkill in the art comparable to that of his brother. As, however, he wrought in the ſame manner, and upon the ſame kind of ſubjects, ſome of his original productions, and many of his copies from Adrian, are palmed upon amateurs as the works of the elder Oſtade. But the diſparity is eaſily diſcernible by the judicious, the touch is not ſo free, the colouring not ſo tranſparent; nor have they an equal warmth or force of effect, in compariſon with each other.

OSTALRIC, in *Geography*, a town of Spain, on the Tordera; 22 miles S.W. of Gerona.

OSTANO, a town of Italy, in the department of the Lario; 10 miles N. of Como.

OSTASCHKOV, a town of Ruſſia, in the government of Tver, near the lake Seliger; 80 miles W. of Tver. N. lat. 56° 50′. E. long. 33° 34′.

OSTBY, a town of Sweden, in Angermanland; 60 miles N. of Hernoſand.

OSTE, a river, which riſes in the S. part of the duchy of Bremen, paſſes by Bremervorde, &c. and runs into the Elbe, at its mouth. N. lat. 53° 54′. E. long. 8° 54′.

OSTELLATO, a town of Italy, in the department of the Lower Po; 14 miles S.E. of Ferrara.

OSTEN, a town of Germany, in the duchy of Bremen; 11 miles N.W. of Stade.

OSTEND, a ſtrong ſea-port of France, in the department of the Lys, and chief place of a canton, in the diſtrict of Bruges. The town contains 10,800, and the canton 12,854 inhabitants, on a territory of 35 kiliometres, in three communes. The harbour is good, and takes its name from its eaſtern ſituation. It is ſurrounded by a great number of forts,

forts, and ten baſtions, and has four gates. This place, which at firſt was a ſmall village, became a town in 1072; and was encompaſſed with walls in 1445 by Philip the Good, who erected gates, enlarged the town, and made the harbour more commodious. It was regularly fortified in 1583 by the prince of Orange. In the year 1601 it was beſieged by the archduke Albert, and in September 1604, above three years after it had been firſt inveſted, the garriſon and inhabitants, who had for this long interval, with equal ſkill and bravery, defended themſelves againſt the moſt vigorous and determined aſſailants, and after a ſacrifice of 100,000 brave ſoldiers, obtained the moſt honourable terms of capitulation. In the year 1706 it was beſieged by ſome troops of the allied army, and after an obſtinate reſiſtance the garriſon ſurrendered on capitulation. The States, having put in a garriſon of their own troops, kept it till the year 1715, when, in conſequence of the barrier treaty, they yielded it up to the troops of the empreſs. In 1722 the court of Vienna eſtabliſhed an Eaſt India company at Oſtend; but in the year 1731 this company was diſſolved. In 1745 Oſtend was taken by the French, but reſtored to the empire at the peace of Aix-la-Chapelle. At the cloſe of the year 1792 it was taken by the French, but evacuated in the following year. In 1711 the preſent town-houſe, which is a magnificent and handſome edifice, was begun and completed. The magiſtracy is compoſed of a bailiff, a burgo-maſter, ſeven echevins, and a treaſurer; the office of bailiff is for life, and the other officers are annually changed. At Oſtend they have no freſh water, which is brought in boats from Bruges, and preſerved in a large reſervoir near the harbour. The town was evacuated by the troops of the allies in July 1794. N. lat. 51° 13′. E. long. 11° 52′.—Alſo, a town of Africa, on the Ivory Coaſt; 30 miles N.E. of Cape Palmas.

OSTENSIO, a tax anciently paid by merchants, &c. for leave to ſhow, or expoſe their goods to ſhow and ſale in markets.

OSTENSIVE Demonstrations, ſuch as plainly and directly demonſtrate the truth of any propoſition.

In which they ſtand diſtinguiſhed from *apagogical* ones, or reductions *ad abſurdum*, or *ad impoſſibile*, which prove the truth propoſed, by demonſtrating the abſurdity or impoſſibility of the contrary.

Oſtenſive demonſtrations are of two ſorts: ſome barely, but directly, prove the thing to be; which they call ὅτι. Others demonſtrate the thing from its cauſe, nature, or eſſential properties; and theſe are called in the ſchools διότι. See Demonstration.

OSTEOCOLLA, ὀστεοκολλα, in *Natural Hiſtory*, a white, or aſh-coloured ſparry ſubſtance, ſhaped like a bone, and by ſome ſuppoſed, without ſufficient reaſon, to have the quality of uniting broken bones; on which account it is ordered in ſome plaſters.

It is found in long, thick, and irregularly-cylindric pieces, which are uſually hollow, but are ſometimes filled up with a marly earth, and ſometimes contain within them the remains of a ſtick, round which the oſteocolla had been formed; but though it is plain from thence, that many pieces of oſteocolla have been formed by incruſtations round ſticks, yet the greater number are not ſo; but are irregularly tubular, and ſeem formed of a flat cake, rolled up in a cylindric ſhape. The cruſts of which theſe are compoſed do not form regular concentric circles round the internal cavity, as muſt have been the caſe had they been formed by incruſtation, but ſhewing plainly that they were once ſo many thin ſtrata, compoſing a flat ſurface, which has afterwards been rolled up as one might do a paper three or four times doubled, into two, three, or more ſpiral lines; in which caſe, each ſingle edge of the paper would be every where a regular part of a continued ſpiral line drawn from a given point; but they would by no means be ſo many detached concentric circles.

The oſteocolla is found of various ſizes, from that of a crow-quill to the thickneſs of a man's arm. It is compoſed of ſand and earth, which may be ſeparated by waſhing the powdered oſteocolla with water, and is found, both in digging and in ſeveral brooks, in many parts of Germany, and elſewhere.

Oſteocolla is called *hammoſteus* in many parts of Germany. It has this name in theſe places from the obſervation of its always growing in ſand, never in clay, or any ſolid ſoil, nor even in gravel. Where a piece of it any where appears on the ſurface, they dig down for it, and find the branches run ten or twelve feet deep. They uſually run ſtraight down, but ſometimes they are found ſpreading into many parts near the ſurface, as if it were a ſubterraneous tree, whoſe main ſtem began at twelve feet depth, and thence grew up in a branched manner, till met by the open air. The main trunk is uſually of the thickneſs of a man's leg, and the branches that grow out from it are thickeſt near the trunk, and thinner as they ſeparate from it. The thinneſt are about the ſize of a man's finger. The people employed to collect this oſteocolla, when they cannot find any mark of it on the ſurface, ſearch after the ſpecks of white or little lumps of whitiſh ſoft matter, which they find lying in different parts on the top of the ſand. Theſe always lead them either to a bed of perfect oſteocolla, or to ſome in the formation. If they miſs of the ſubſtance which they ſeek after, they ſtill find the ſubſtance like rotten wood; which, when traced in its courſe, is found to proceed from a main trunk, at the depth of that of the oſteocolla, and to ſpread itſelf into branches in the ſame manner. The diggers call this ſubſtance the flower of oſteocolla, or hammoſteus.

The oſteocolla found in the earth is at firſt ſoft and ductile, but in half an hour's time, if expoſed to the air, it becomes as hard as we find it in the ſhops. The method to take up a perfect piece for a ſpecimen is to open the ground, clear away the ſand, and leave it ſo for an hour or thereabouts: in this time it will harden, and may be taken out whole. It is certain that the oſteocolla is produced at this time; for, if a pit be cleared of it, there will more grow there in a year or two, but with this difference, that it will be ſofter and will not harden ſo eaſily in the air as the other. What the rotten ſubſtance reſembling the decayed branches of trees is, it is not eaſy to ſay, unleſs it really be ſuch: but the opinion of the common people, that it is the root of ſomething, is abſurd; becauſe its thickeſt part always lies at the greateſt depth, and the branches all run upwards. The oſteocolla is a marly ſpar, which concretes round this matter; but what it is that determines it to concrete no where on the ſame ground but about theſe branches it is not eaſy to ſay. The rottenneſs of this ſubſtance, which forms the baſis of the oſteocolla, renders it very liable to moulder and fall away; and hence it is that we uſually ſee the oſteocolla hollow. Sometimes it is found ſolid, but in this caſe there will be found to have been a vegetable matter ſerving as its baſis, and inſtead of one branch, it will be found in this caſe to have concreted about a number of fibres, the remains of which will be found in it on a cloſe examination. Phil. Tranſ. N° 39.

Osteocolla-*Flower*. See Flower.

Osteocolla-*Root*. See Root.

OSTEOCOLLON, in *Botany*, a name given by ſome authors to the great comfry.

This

This name was given by ſome of the old writers to the ſymphytum, or comfry, from an opinion that its agglutinating quality reached to the bone, and that it was of great ſervice taken internally, in caſes of fractures.

OSTEOCOPOS, or OSTOCOPOS, formed from οστεον, *bone*, and κοπτειν, *to break*, *cut*, or *cleave*, is uſed by ſome for an acute pain, in which the patient is affected as if his bones were breaking.

It riſes from a ſharp humour vellicating the perioſteum, or membrane, with which the bones are inveſted. It is particularly incident to ſcorbutic and pocky perſons.

OSTEOGENIA is a technical term applied to the formation of the bones.

OSTEOGONY. See OSSIFICATION.

OSTEOGRAPHIA is a deſcription of the bones; a title which has been given to ſome anatomical works.

OSTEOLOGY is that diviſion of *Anatomy* which treats of the bones. The organiſation of the bones, and the progreſs of their formation, have been conſidered under the articles BONE in *Anatomy*, BONE in *Chemiſtry* and the *Arts*, and EMBRYO. The particular bones are deſcribed in various articles of this work: thoſe of the head in CRANIUM; of the vertebral column in SPINE; of the cheſt in LUNGS; and of the limbs in EXTREMITIES. A deſcription of the marrow will be found under MEDULLARY *Syſtem*; and for the articulations by which the bones are connected, ſee JOINT.

OSTEOSARCOMA, or OSTEOSARCOSIS, in *Surgery*, a ſwelling, the conſiſtence of which is partly bone and partly fleſh. Alſo the diſeaſe called *mollities oſſium*.

OSTEOSPERMUM, in *Botany*, ſo named in alluſion to its hard, bony ſeeds, and derived from οστεον, *bony*, and σπερμα, *ſeed*. Linn. Gen. 448. Schreb. 585. Willd. Sp. Pl. v. 3. 2365. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 275. Juſſ. Gen. 183. Lamarck Dict. v. 4. 659. Illuſtr. t. 714. Gærtn. t. 168. (Monilifera; Vaill. Mem. Par. 1720. f. 28. Chryſanthemoides; Tournef. Mem. Par. 1705. f. 4. Dill. Gen. 9. Elth. 68.)—Claſs and order, *Syngeneſia Polygamia Neceſſaria*. Nat. Ord. *Compoſitæ Diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* ſimple, hemiſpherical, of numerous, awl-ſhaped, minute leaves. *Cor.* compound, radiated; *florets* of the diſk perfect, numerous, tubular, five-toothed, the length of the calyx; thoſe of the radius female, about ten in number, ligulate, linear, three-toothed, very long. *Stam.* (in the perfect florets) Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* (in the perfect florets) Germen very ſmall; ſtyle thread-ſhaped, ſcarcely as long as the ſtamens; ſtigma emarginate: the female or ligulate florets differ in having their germen globoſe and a ſomewhat longer ſtyle. *Peric.* none, except the unchanged calyx. *Seeds* (in the perfect florets) none: (in the female ones) ſolitary, nearly globoſe, coloured, indurated by age, and incloſing a kernel of the ſame ſhape. Down none. *Recept.* naked, flat.

Eſſ. Ch. Receptacle naked. Down none. Calyx of many leaves. Seeds globular, coloured, bony.

Obſ. Of this extenſive and rather ſhowy genus we find only twelve ſpecies deſcribed in the *Species Plantarum*. In the 14th edition of *Syſt. Veg.* fifteen are enumerated, and to theſe Profeſſor Martyn has added two more. Willdenow however has extended the genus to twenty-three ſpecies, from which we ſelect the following for illuſtration.

O. *ſpinoſum*. Prickly Oſteoſpermum. Linn. Sp. Pl. 1308. Jacq. Hort. Schoenbr. v. 3. 66. t 377.—Leaves obovate, ſerrated, downy. Permanent flower-ſtalks ſpinous.—Native of the Cape of Good Hope, flowering in September and October. *Stem* round, branched, erect, from two to ſix feet high, ſhrubby, denudated and ſcarred when old. *Branches* woolly when young, rather rigid, terminating in ſpinous, branched ſtalks, each bearing one flower. *Leaves* ſcattered, on ſtalks, attenuated at their baſe, obtuſely pointed, thickiſh, ſlightly webbed with down, glaucous. *Flowers* ſtar-like, ſolitary, yellow, having a ſweet ſmell.

O. *piſiferum*. Smooth Oſteoſpermum. Linn. Sp. Pl. 1308. (O. fruticans, lanuginoſum, foliis oblongis dentatis; Burmann. Afric. 171 t. 61. f. 2.)—Leaves ovato-lanceolate, pointed, ſlightly ſtalked, ſmooth, ſerrated.—This native of the Cape was cultivated in 1757, by Mr. Philip Miller. *Stem* four or five feet in height, much branched upwards, in a ſpreading manner. *Bark* purpliſh. *Leaves* thick and ſucculent, alternate, light green. *Flowers* ſolitary, yellow, on long, axillary ſtalks. *Seeds* oval, at firſt green, then red, and afterwards dark purple.

O. *moniliferum*. Poplar-leaved Oſteoſpermum. Linn. Sp. Pl. 1308. (Chryſanthemoides africanum, populi albæ foliis; Tournef. Dill. Elth. v. 1. 80. t. 68. f. 79.)—Leaves obovate, ſerrated, ſtalked, ſomewhat decurrent.—Native of the Cape. It was introduced into this country in 1714, though it flowers but rarely. *Stem* ſhrubby, ſeven or eight feet in height, much branched, and covered with a ſmooth grey bark. *Leaves* alternate, very thick and fleſhy, covered with a hoary down; their ſtalks, according to Linnæus, have a knob under their baſe. *Flowers* cluſtered, at the ends of the branches, yellow, reſembling thoſe of *Senecio Jacobæa*.

O. *ilicifolium*. Holly-leaved Oſteoſpermum. Willd. n. 5. (O. foliis ſcabris, ſinuoſis, denticulatis; Burmann. Afric. 172. t. 62.)—Leaves oblong, with angular teeth, rough, half embracing the ſtem. Branches furrowed.—Native of the Cape of Good Hope. *Stem* ſhrubby, branched, about two feet high, rather lax. *Leaves* ſhaped much like thoſe of our Common Holly, ſeſſile, involute at the margin, rough on the upper ſide, villoſe and almoſt woolly beneath. *Flowers* terminal, ſtalked, yellow.

O. *cæruleum*. Blue-flowered Oſteoſpermum. Willd. n. 7. Jacq. Ic. Rar. v. 1. t. 179. (O. pinnatifidum; L'Herit. Stirp. Nov. 11. t. 6.)—Leaves pinnate; ſegments toothed.—Native of the Cape. It flowers with us from June to September. This ſhrub is about three feet in height, with a ſtrong ſmell. *Root* woody, branching, fibrous. *Stem* woody, erect, round, regularly branched, grey. *Leaves* pinnate, alternate, ſpreading; ſegments oblong, acute, ſerrated; ſtalks half the length of the leaves, ſcarcely downy. *Flowers* terminal, in a looſe corymb, ſtalked, erect, blue. *Seeds* ſomewhat angular and rugged, but, according to L'Heritier, not at all bony.

The remaining ſpecies of *Oſteoſpermum* which occur in Willdenow, and which do not appear to be anywhere figured, are as follows. *O ſpineſcens*, *rigidum*, *bipinnatum*, *arctotoides*, *perfoliatum*, *niveum*, *herbaceum*, *hirſutum*, *Bidens*, *ciliatum*, *junceum*, *corymboſum*, *ſcabrum*, *incanum*, *triquetrum*, *tereti-folium*, *imbricatum*, and *polygaloides*. They are all natives of the Cape of Good Hope, and all, except *rigidum*, are taken from Thunberg's Prodromus.

OSTEOSPERMUM, in *Gardening*, compriſes plants of the ſhrubby exotic kind for the greenhouſe, of which the ſpecies cultivated are; the prickly oſteoſpermum (O. ſpinoſum); the ſmooth oſteoſpermum (O. piſiferum); the poplar-leaved oſteoſpermum (O. moniliferum); and the blue-flowered oſteoſpermum (O. cæruleum).

Method of Culture.—Theſe plants may be increaſed by cuttings of the young ſhoots, which may be planted in any of the ſummer months, upon a bed of light earth, being watered

watered and ſhaded until they have taken root, when they muſt be taken up and planted out ſeparately in pots; as when they are ſuffered to ſtand long, they are apt to make ſtrong vigorous ſhoots, and be difficult to tranſplant afterward, eſpecially the ſecond and third ſorts; but there is not ſo much danger of the firſt, which is not ſo vigorous, nor ſo eaſy in taking root as the other. In the ſummer ſeaſon the pots ſhould be frequently removed, to prevent the plants from rooting through the holes in the bottoms of the pots into the ground, which they are very apt to do when they continue long undiſturbed, and when they ſhoot very luxuriantly; and on their being removed, theſe ſhoots, and ſometimes the whole plants, are deſtroyed.

As the plants are too tender to live in the open air in this climate, they ſhould be placed in the greenhouſe in October, and be treated in the ſame manner as myrtles, and other hardy greenhouſe plants, which require a large ſhare of air in mild weather; and in the beginning of May the plants removed into the open air, and placed in a ſheltered ſituation during the ſummer ſeaſon. As the firſt and ſecond ſorts are very thirſty plants, they ſhould have plenty of water.

Theſe plants afford variety among others of the greenhouſe kind.

OSTER, in *Geography*, a town of Ruſſia, in the government of Kiev, at the conflux of the rivers Oſter and Deſna; 24 miles N. of Kiev. N. lat. 50° 58′. E. long. 31° 14′.

Oster *Cappeln*, a town of Weſtphalia, in the biſhopric of Oſnabruck; 10 miles E.N.E. of Vorden.

Oster *Oen*, an iſland near the coaſt of Norway; 20 miles N.W. of Bergen.

OSTERBURG, a town of Weſtphalia, in the Old Mark; 36 miles N.W. of Brandenburg. N. lat. 52° 48′. E. long. 11° 56′.

OSTERBY, a town of Sweden, in the province of Upland, remarkable for its furnaces, and near the iron-mine of Dannemora, which is one of the largeſt and richeſt in Sweden; 24 miles N. of Upſal. See Dannemora.

OSTERFELS, a town of Saxony, in the biſhopric of Naumburg; 7 miles S.E. of Naumburg. N. lat. 51° 5′. E. long. 11 53′.

OSTERHOFEN, a town of Bavaria, on the Danube, 20 miles N.W. of Paſſau.

OSTERHOLZ, a town of the duchy of Bremen, the inhabitants of which are employed in digging peat or turf, which they ſell, to the annual amount of 18,000 rix-dollars, to the people of Bremen; 7 miles E. of Bremen.

OSTERLOF, a town of Sweden, in the province of Schonen; 8 miles N. of Chriſtianſtadt.

OSTERMAN, *Count*, in *Biography*, a celebrated Ruſſian miniſter, was the ſon of a clergyman at Bockhum in Weſtphalia. Being, in his youth, taken into the ſervice of the Ruſſian admiral Cruys during his reſidence in Holland, he accompanied that officer in 1704 as his private ſecretary. In the courſe of a few years, he was preſented by the admiral to Peter the Great, as every way qualified to write his diſpatches; his firſt eſſay ſo well pleaſed his ſovereign, that he immediately made him his ſecretary, and in this ſituation he ſoon gained the confidence of his employer. He thus roſe, ſtep by ſtep, to the moſt important offices in the government, and the emperor was ſo much his friend, that he brought about a marriage between him and a lady connected with ſome of the nobleſt families in Ruſſia. He preſerved his influence in Ruſſia during the reigns of ſeveral ſovereigns; but in the revolutions that placed the empreſs Elizabeth on the throne, he became involved in the ſame diſgrace as counts Munic and Lowenwolde. He was even condemned to ſuffer death, but his puniſhment was commuted for perpetual baniſhment in the deſolate regions of Siberia, where he died in the year 1747, in the ſame place where Mentizoff had ended his days ſome years before. After his death his wife and family were recalled, and their property and rank reſtored to them. Count Oſterman poſſeſſed a ſound judgment, and was capable of the moſt indefatigable labour; no miniſter of the ſame period was ſo well acquainted with the intereſts of the different courts of Europe, and in the exerciſe of his official duties none could be more diſintereſted and incorruptible; but he was ſuſpicious and overbearing, and he expected all his coadjutors to give way to whatever he propoſed. This, however, is very generally the caſe with great minds. "His mode of expreſſing himſelf," ſays his biographer, "was ſo artful and obſcure, that few could flatter themſelves that they were able to diſcover his true meaning. His ſtyle alſo, in general, was ſo ambiguous, that whatever he wrote might be explained two different ways. Though he was completely maſter of his feelings, and would appear to participate in things which were contrary to his conviction, he was ſo much afraid of betraying his real ſentiments by external emotions, that he never looked thoſe full in the face with whom he converſed." Gen. Biog.

OSTERMARK, in *Geography*, a town of Sweden, in Eaſt Bothnia; 18 miles N.E. of Chriſtianſtadt.

OSTERO, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63° 23′. E. long. 21° 39′.

OSTEROD, a town of Norway; 28 miles N.N.W. of Drontheim.

OSTERODE, a town of Weſtphalia, in the principality of Grubenhagen, on the Saal, containing about 800 houſes, and a magazine of corn, which is delivered out to the miners of Harz foreſt always at a fixed price. The town has alſo a manufacture of woollen ſtuffs; 16 miles W. of Goſlar. N. lat. 51° 44′. E. long. 10° 6′.

OSTEROE, one of the Faroe iſlands, E. of Stromoe, and ſeparated from it by a narrow channel. N. lat. 61° 50′.

OSTERRODE, a town of Pruſſia, in the province of Oberland, on the river Dribentz, defended by a caſtle; 45 miles S.E. of Dantzic. N. lat. 53° 36′. E. long. 19° 52′.

OSTERSUND, a town of Sweden, and capital of Jamtland, on the E. ſide of the lake Storſio; 95 miles W.N.W. of Hernoſand. N. lat. 63° 10′. E. long. 14° 27′.

OSTERSUNDAM, a town of Sweden, in the province of Nyland; 9 miles N.E. of Helſingfors.

OSTERTZ, a town of Croatia; 14 miles S.W. of Varaſdin.

OSTERWALD, John Frederic, in *Biography*, was born at Neufchatel in the year 1663. He commenced his academical ſtudies at Saumur, and ſo rapid was the progreſs which he made in them, that he was admitted to the degree of M. A. before he was ſixteen years of age. He afterwards purſued his ſtudies at Orleans and Paris, and was admitted to the office of the miniſtry. He ſettled as paſtor to the church of his native place in 1699, and contracted an intimate friendſhip with the celebrated John Alphonſus Turretin of Geneva, and Samuel Werenfels of Baſil, and the union of theſe three theologians, which was called *the triumvirate of Swiſs divines*, laſted till their deaths. Oſterwald died in 1747, at the age of 84. He was author of ſeveral uſeful works written in the French language, of which the principal are; 1. A Catechiſm of the Chriſtian Religion; 2. Arguments and Reflections on the Books of the Bible; 3. Treatiſes on Uncleanneſs, and on the Sources of Corruption; and 4. A Collection of Sermons. His ſon, John Rodolph Oſterwald, was paſtor of the French church at Baſil. Moreri.

OSTERWICK, in *Geography*, a town of Pomerelia; 10 miles S.S.E. of Dantzic.—Alſo, a town of Weſtphalia, in the principality of Halberſtadt, ſeated on the Ille, containing ſeveral woollen manufactures; 15 miles N.E. of Goſlar. N. lat. 51° 59′. E. long. 10° 33′.

OSTHAMMAR, a ſea-port of Sweden, in the province of Upland, formerly a ſtaple-town, ſituated on a ſmall rocky iſland, called "Gold Sheor," in the Aland's Haff, near the coaſt; 30 miles N.E. of Upſal. N. lat. 60° 15′. E. long. 18° 19′.

OSTHEIM, a town of Germany, in the county of Henneberg; 8 miles S.W. of Meinungen.

OSTIA, in *Anatomy*, a term uſed indifferently with oſcula, orifices, &c. for the mouths or apertures of the body; as the *oſtia vaginæ*, &c.

Ostia, or *Oſti*, in *Geography*, a ſea-port town of Italy, and the ſee of a biſhop, ſituated 13 miles from Rome, at the mouth of the Tiber, whence it derived its name. This port was firſt conſtructed and the town ſurrounded by walls, in the time of Ancus Martius. The harbour was reckoned one of the moſt magnificent and ſtupendous of the Roman works; but it was ruined by the accumulation of ſand, and by the change of the courſe of the river, which ran into the ſea by another arm. In the 16th century, when the remains of this Auguſtan port were ſtill viſible, the antiquarians ſketched the plan (ſee d'Anville, Mem de l'Acad. des Inſcriptions, tom. xxx. p. 198.) and declared, with enthuſiaſm, that all the monarchs of Europe would be unable to execute ſo great a work. Oſtia Tiberina, the two mouths of the Tiber, were ſeparated by Holy Iſland, of an equilateral form, each of whoſe ſides was eſtimated at two miles. In the time of Strabo, the harbour was ſo choaked, that the iſland was augmented, and the town and port were left at a conſiderable diſtance from the ſhore.

In the third or fourth century, Oſtia was erected into a biſhopric; the old town was deſtroyed by the Saracens; and the new one conſiſts only of a cathedral, and of a few mean houſes built round it. The air here is very indifferent. N. lat. 41° 46′. E. long. 12° 13′.

OSTIAKS, a denomination comprehending three tribes of people, connected with the Finns and the Samoyedes. In the conqueſt of Siberia, by the Tartars, they contemptuouſly called all the inhabitants of this extenſive country, whilſt they knew only a ſmall part of it, "Uſchtyæk," a word denoting a foreigner or barbarian. This denomination was at firſt retained by the Ruſſians from ignorance, and has been ſince loſt in proportion as the diverſity of the Siberian nations has been detected. At preſent there remain three very diſtinct people, both in deſcent and language; *viz.* the Oſtiaks of the Oby, of the Marym, or Narym, and of the Yeniſſey; the firſt of theſe tribes belongs to the ſtock of Finns. The Oſtiaks of the Southern Oby call themſelves Aſyaks, from the river Oby, which in their language is called Yak; the northern, Khondi Khui, people of Konda, becauſe they withdrew from that river towards the north. Both ſtems dwell at preſent about the Oby and the Irtiſh, in the government of Tobolſk, and derive their origin from the Permians, from whom they probably ſeparated to avoid biſhop Stephen's barbarous zeal for making converts. If this derivation were as certain as it is probable, from the ſimilitude of the languages, they muſt ſurely have had ſome very urgent motive for quitting their mild and gentle ſky on the W. ſide of the Ural, for the inclement regions of the Oby. The Oſtiaks of the Oby are held to be one of the moſt numerous of the Siberian nations; but accurate ſtatements of the amount of their population are wanting.

The Narym Oſtiaks, who are alſo called Moraſes, are about the upper parts of the Surgut, in the diſtricts of the Oby quite to the Narym, and about the mouths of the rivers Ket and Tom.

The Yeniſſey Oſtiaks, though they reſemble the two other nations of that name in appellation and mode of life, yet ſpeak a language ſo entirely different from that of the Oſtiaks, as well as from all the Siberian tongues, that they might rather be taken for races of a particular nation, though not the ſmalleſt indications of their origin have been hitherto diſcovered. Theſe dwell about the inferior Yeniſſey, near and between the Samoyedes. When the Ruſſians, in the 17th century, had extended their conqueſt hither, theſe Oſtiaks not only immediately ſubmitted, but alſo aſſiſted the Ruſſians to ſubdue the neighbouring nations. In proportion to the dimenſions of the ground they occupy, they are not numerous. Tooke's Ruſſ. vol. i.

OSTIANO, a town of Italy, in the department of the Upper Po; 12 miles N.E. of Cremona.

OSTIANY, a town of Lithuania, in the palatinate of Wilna; 40 miles S.E. of Wilna.

OSTIARY, one of the five inferior orders in the Roman church, whoſe office is to keep the doors of the church, and to toll the bell.

OSTICO, in *Geography*, a ſmall lake of America, in Onondago county, New York, which ſends its waters from the N. end by a ſtream 16 miles long to Salt lake.

OSTIGLIA, a town of Italy, in the department of the Mincio; 10 miles E.S.E. of Mantua.

OSTIMURI, a town of New Mexico, in the province of Hiaqui; 40 miles E. of Riochico. N. lat. 29° 12′. W. long. 110° 56′.

OSTINATO, Ital., in *Muſic*, obſtinate, perſevering in a theme or ſubject, without variety.

OSTINES, or Charlestown, in *Geography*, a conſiderable town in the iſland of Barbadoes.

OSTINGHAUSEN, a town of Germany, and ſeat of a prefecturate, in the duchy of Weſtphalia; 8 miles W. of Lippſtadt.

OSTIONES, a ſmall iſland in the Pacific ocean, near the coaſt of America. N. lat. 4° 10′.

OSTRACH, a river of Germany, which runs into the Danube, about a mile below Scheer.

OSTRACION, or *Trunk-fiſh*, in *Ichthyology*, a genus of fiſhes of the order Branchioſtegous, of which the generic character is; teeth round, pointing forwards, blunt; aperture of the gills linear; body mailed by a complete bony covering. It has no ventral fins. There are twelve ſpecies, which are as follow:

Species.

Triqueter. The ſpecific character of this is, that it is triangular-bodied, and unarmed. It is about twelve inches in length, and is, as its name imports, of a trigonal ſhape, the ſides ſloping obliquely from the ridge of the back, and the abdomen being flat: the whole animal, except to within a ſmall diſtance from the tail, is completely enveloped in a bony covering, divided into hexagonal ſpaces, and covered, as is the caſe in the whole genus, with a tranſparent epidermis, like that of the armadillo among quadrupeds: the uſual colour is a ſubferruginous brown, with a white ſpot in the centre of each hexagon, which is alſo marked by fine rays diverging from the centre to the edges. It is a native of the Indian and American ſeas, and is ſuppoſed to feed on ſmaller cruſtacea, ſhell-fiſh, and ſea-worms. It is conſidered as an excellent fiſh for the table, and is held in high eſtimation among the inhabitants of India.

Trigonus. Triangular; two ſubcaudal ſpines; the dor-

ſal

ſal fin is fourteen-rayed. It inhabits India. It is ſaid to make a kind of grunting noiſe when firſt taken, owing to the ſudden exploſion of air from its branchial orifices.

Biaculeatus. This is the triangular-bodied trunk-fiſh, with two ſubcaudal ſpines, and ten rays in the dorſal fin. There is a variety, the body of which is covered with ſpots and tubercles. They are found in India, and are thought by ſome naturaliſts to be varieties of the O. trigonus.

Tricornus. Triangular, with two frontal ſpines and one dorſal. It is about ten inches long; in the front of the head there are two ſhort pointed ſpines, directed forwards; above the naked part of the body, near the tail, is a long upright pointed ſpine: the ſhield is divided into hexagons, each obſcurely marked into triangular ſpaces. It is a native of India.

Quadricornus. Triangular, with two frontal and ſubcaudal ſpines. It inhabits India and Guinea.

Turritus. This is nearly quadrangular; the eye-brows and back with a ſingle ſpine; the belly with four on each ſide. It inhabits the Red ſea, and is four inches long; the body tuberculate, yellowiſh-aſh, brown on the naked parts; the bony coat is divided into hexagonal pieces, that are rough with numerous elevated dots, the ſutures pellucid; the ſhell of the belly very broad, flat, oval, tapering on the fore-part, and obtuſe behind; the back is convex, marginate at the ſides; the middle is gibbous, compreſſed, triangular, with an erect ſhort ſpine, turned back; the front is perpendicular, rounded, convex, depreſſed beneath the eyes; the iris is golden.

Cornutus. Quadrangular-bodied trunk fiſh, with two frontal and two ſubcaudal ſpines. The length of this fiſh is about eight or ten inches; the ſhape is ſquariſh; broad and abrupt towards the head, and tapering conſiderably towards the hind part; the back is nearly ſtraight; the cruſt or mail is ſtrongly marked into large hexagons; from the top of the head project two ſtrong, lengthened, ſharp ſpines, pointing ſtraight forwards; and on each ſide the anal fin is a ſimilar ſpine pointing directly backwards; the tail is long, large, and of an oval ſhape; the colour of the whole animal is yellowiſh-brown, and deeper beneath; the tip of the tail is duſky. It is a native of the Indian and American ſeas.

Auritus. Brown; one ſpine over each eye; two on each ſide the back, and two on each ſide the belly. It inhabits near the iſlands of the Pacific ocean, was obſerved during the voyages of captain Cook, and a ſpecimen is preſerved in the Britiſh Muſeum.

Tuberculatus. Quadrangular, unarmed, with four dorſal tubercles. It inhabits India.

Gibbosus. Quadrangular, unarmed, gibbous. It inhabits Africa, and is thought to be a variety of O. triqueter above deſcribed.

Cubicus. Quadrangular, unarmed; ſides flattiſh. It reſembles the O. triqueter, but has a ſquare body. The mail is marked into tuberculated hexagons, each of which has a white or blueiſh central ſpot, ſurrounded with a darker border: the ground colour of the whole mailed part is a pale yellowiſh-brown; of the naked or projecting part towards the tail yellowiſh-brown, with a few duſky variegations; the tail and fins are of a reddiſh-brown. It is a native of the Indian ſeas, and is ſaid to be an excellent fiſh for the table, and to be kept for that purpoſe in reſervoirs, growing ſo familiar as to come at a given ſignal to the ſurface of the water, and take its food from the hand.

Meleagris. This is ſomewhat ſquare; blackiſh, ſpeckled with white. It inhabits the Southern ocean; is from ſix to eight inches long, and beautifully marked with almoſt innumerable white ſpots. It is a native of the Indian ſeas, and was often obſerved during captain Cook's voyages about the coaſts of New Holland, Otaheite, &c.

Theſe are the ſpecies enumerated in Gmelin's edition of Linnæus; we ſhall now mention three others deſcribed in Dr. Shaw's Zoology.

Concatenatus; Triangular-bodied unarmed trunk-fiſh, with whitiſh concatenated variegations. The habit of this ſpecies is very like to that of the trigonal and triangular trunk-fiſh, but with a leſs elevated back; the mail is marked into triangular, ovate, and other ſhaped ſpaces, in a kind of reticular pattern; the colour is brown, the lines dividing the ſpaces being of a pale roſe-colour; the fore-parts and abdomen of the ſame colour; the end of the body is brown; tail and fins pale brown. It is a native of the American ſeas.

Nasus; Whitiſh ſubquadrangular-bodied trunk-fiſh, with brown concatenated variegations. The habit of this is approaching to that of the preceding ſpecies, but more ſlender; the head is very convex; the colour is greeniſh-white, or aſh, with the mail marked into very large hexagons, by means of broad, ovate-lanceolate, blackiſh lines, with ſimilar ones radiating from the centre of the hexagons, and thus elegantly dividing the whole into triangles, with finer lines or margins accompanying each; the naked or projecting part of the body, towards the tail, is marked with round black ſpots; the fins and tail are of a reddiſh-brown. It is a native of the Indian and American ſeas.

Striatus. Trunk-fiſh with yellow and blue ſtripes, and a ſpine over each eye, two on each ſide the back and abdomen, and one on each ſide the body. This in ſize and habit is very like the O. auritus; the colour is a beautiful variation of bright blue and yellow, in the form of lines diſpoſed in different directions, but principally in a longitudinal one over the whole fiſh; above each eye is a ſtrong ſpine, as in the auritus. On the ridge of the back are two pair, diſpoſed as in that ſpecies; and on each ſide the abdomen there are three, the middle of which is higher than the reſt. It is doubted whether this fiſh be a mere ſexual difference of the preceding: or, it is thought the auritus may be in reality no other than the preſent animal changed in colour, from the circumſtance of its having been long preſerved in ſpirits of wine. It was obſerved by Capt. G. Tobin, about the coaſts of Adventure bay, in Van Diemen's land.

OSTRACISM, *οστρακισμος*, a kind of popular judgment or condemnation among the Athenians; being a ſentence of baniſhment againſt perſons, whoſe too great power rendered them ſuſpected to the people; or whoſe merit and credit gave umbrage leſt they ſhould attempt ſomething againſt the public liberty, and their power degenerate into tyranny.

It had the denomination oſtraciſm, becauſe the people gave their votes, by writing the name of the perſon to be baniſhed in a ſhell, by the Greeks called *οστρακον*, and caſting the ſhells into an urn.

This kind of baniſhment had nothing infamous in it, as not being for a crime; but, on the contrary, was held very honourable, as it was a mark of popularity.

It laſted for ten years; but the baniſhed perſon had the full enjoyment of his eſtate all the time.

Oſtraciſm was null, unleſs there were 6000 citizens in the aſſembly of the people, whereby it was decreed.

OSTRACITES, in *Natural Hiſtory*, a name given by authors to the foſſile oyſters, common in many parts of England. Theſe are of various ſhapes and kinds; and the name is by ſome authors made to ſignify the ſhell itſelf, when preſerved in its native ſtate and condition; as is the caſe with thoſe found about Woolwich and Blackheath; and by

others, the ſtones caſt or formed in thoſe ſhells, or in cavities from whence they have been waſhed away and diſſolved: in both theſe caſes the ſtone carries the exact reſemblance of the ſhell, even in its niceſt lineaments; in the firſt caſe, bearing every mark of the inſide, in the other of the outer ſurface. We have this ſtone in great plenty in many parts of England; and it is very famous, in ſome places, for its virtues in caſes of the gravel, and the like complaints.

It is to be obſerved that all the foſſile ſhells, and particularly the *lapides Judaici*, or Jew's ſtones, which have been the ſpines of ſea echini, have been eſteemed diuretics, and good in the ſtone and gravel. Among the ancients, Dioſcorides, Pliny, and all the reſt, recommend them highly.

Dr. Home, in the Philoſ. Tranſ. ſays, the oſtracites rather diſſolves the little ſtones than forces them out, as not being remarkably diuretic. He adds, that he preſcribes it in powder, with a third part of flores chamæmeli. The doſe is from half a drachm to a whole one, in white wine.

Ostracites is alſo the name of a kind of cadmia, found at the bottom of furnaces where copper is purified. It is very heavy, and in ſtructure reſembles an oyſter-ſhell; whence its name.

It has been eſteemed aſtringent and deterſive; and introduced as an ingredient in ſeveral unguents.

OSTRACODERMATA, a term uſed by Ariſtotle to expreſs that claſs of ſhells which we call *teſtaceous*, in oppoſition to the cruſtaceous animals, or malacoſtraca.—The definition Ariſtotle gives of this claſs of animals is, that they are ſoft within, but hard without; that their ſhells may be bruiſed or broken, but their parts cannot be torn from one another, as they can in the cruſtaceous kind, ſuch as the lobſter; whoſe ſhell covering the legs, body, tail, &c. being ſo many diſtinct pieces of ſhell, and only joined by membranes, may be torn aſunder by pulling till thoſe membranes give way. Philoſ. Tranſ. N° 219. p. 199.

OSTRAU, or Ostrow *Mahriſch*, in *Geography*, a town of Moravia, in the circle of Prerau, on a river of the ſame name, on the borders of Sileſia; 20 miles S.E. of Troppau. N. lat. 49° 47'. E. long. 18° 17'.

Ostrau, a town of Moravia, in the circle of Hradiſch, on an iſland in the river Marſch; 7 miles S. of Hradiſch.

OSTRAVA, or Ostrawiec, a river which ſeparates the principality of Teſchen from Moravia, and runs into the Oder, 5 miles S. of Oderburg.

OSTREA, the Oyſter, in *Natural Hiſtory*, a genus of the claſs and order Vermes Teſtacea. Animal a tethys; ſhell bivalve, generally with unequal valves, and ſlightly eared; hinge without teeth, but furniſhed with an ovate hollow, and moſtly lateral tranſverſe grooves. Of this genus there are one hundred and thirty-ſix ſpecies, divided into two ſections, which ſections are likewiſe ſubdivided. Moſt of the ſpecies of this genus are furniſhed at the hinge internally with numerous parallel internal grooves in each valve, and they are diſtinguiſhed from the genus Arca, in not having teeth alternately locking in each other.

Section A. The ſpecies in this ſection have valves furniſhed with ears and radiate; denominated Scallop. Theſe leap out of the water to the diſtance of half a yard, and opening the ſhells, eject the water within them; after which they ſink under water, and ſuddenly cloſe the ſhells with a loud ſnap. This ſection is ſubdivided into three ſubſections, viz. (*a*) equilateral; ears of the valves equal, containing forty ſpecies: (*b*) ears unequal, one of them generally ciliate with ſpines within, containing fifty-four ſpecies: and (*c*) valves more gibbous on one ſide; in this ſubſection there are ſeven ſpecies.

a. Equilateral; ears of the valves equal.

Species.

* Maxima. Shell with fourteen rounded longitudinally ſtriate rays. This is delineated by Mr. Donovan in his Britiſh Shells. There are two other varieties deſcribed by Liſter and Knorr. Theſe are found in moſt European ſeas, in large beds; whence they are dredged up, and pickled and barrelled for ſale. This is the ſhell that was formerly worn by pilgrims on the hat or coat, as a mark that they had croſſed the ſea, for the purpoſe of paying their devotions in the Holy Land, in commemoration of which it is ſtill preſerved in the arms of many families. The ſhell is five or ſix inches long, and rather broader; the ears are large, with decuſſate ſtriæ; the hinge with a large deep hollow; lower valve convex, white, often varied with red bands or ſpots; the upper valve is flat and reddiſh.

* Jacobæa. Shell with about fourteen angular and longitudinally ſtriate rays. It inhabits European ſeas, and is leſs than the laſt. The grooves of the ſhell are tranſverſely ſtriate; the upper valve is flat; the lower valve with angular rays; the ears are concave and ſmooth on the upper ſide.

Ziczac. Shell with flattened rays. It inhabits the American ocean; ſometimes of one colour, ſometimes variegated; the ears are very finely wrinkled; the lower valve is convex, with from eighteen to twenty rays, which are very finely ſtriate tranſverſely, and about twice the number of perpendicular ſtriæ within. The upper valve is flat.

Striatula. Shell with ſixteen faint rays with tranſverſe membranaceous ſtriæ; the margin very entire. It is found in the Indian ocean. The ſhell is middle-ſized, varied with purple and white, within yellowiſh.

Minuta. Shell with twenty convex rays. It inhabits the Indian ocean. The ſhell is about the ſize of a nut; lower valve white and very convex; upper valve white clouded with brown, flatter and plaited.

Pleuronectes. Shell equivalve, with twelve doubled rays, and ſmooth on the outſide. It inhabits the Indian ocean; it is ſometimes reddiſh, or of a fleſh-colour, or liver-colour; within it is ſilvery. There is a variety of an orange-colour radiate with red; it is four inches and a half long, and gaping at each end.

Laurentii. Upper valve ſub-convex, ſmooth, with fine perpendicular lines croſſing very fine concentric tranſverſe ſtriæ; lower valve with twenty-four rays and forty-eight ſtriæ within. It is found on the ſhores of South America, and is very rare. The ſhell is nearly three inches long, and about as broad.

Japonica. Shell equivalve, a little convex, margined with yellow; upper valve with faint lines croſſing concentric tranſverſe bands, and forty elevated ſtriæ within. It is found on the ſhores of Guinea and Japan; is about five inches and a half long and broad, and reſembles the O. pleuronectes, but is coarſer and thicker.

Magellanica. The ſhell of this is likewiſe equivalve, glabrous, with oblong crowded ſtriæ. It is found in the ſtraits of Magellan; it reſembles the O. pleuronectes. The ſhell is lateritious, not radiate, quite ſmooth within; upper valve more convex; lower valve flatter than in moſt others, the ears are tranſverſely ſtriate.

Hybrida. Shell with nine or ten rays, the interſtices longitudinally ſtriate; margin repand within. It inhabits the Norway ſeas; thin, lower valve white, upper valve ſanguineous, with angular veins and lines.

Radula. Shell nearly equivalve, with twelve convex rays croſſed by crenate ſtriæ. It is found in the Indian ocean;

ocean; is three inches and a quarter long, and two and a half broad. The ſhell is oblong, white, or varied with white and brown; the lower valve is a little more convex; ears wrinkled and furrowed with oblique ſtriæ.

IMBRICATA. Shell nearly equivalve, with nine unequal rays imbricate with ſcales. It is found on the ſhores of the Red ſea, and reſembles the laſt. The colour of the ſhell is whitiſh with purple ſpots, and a little crenate at the margin; the rays alternately larger.

SUBROTUNDA. Shell roundiſh, with eight convex cheſnut rays; ears roundiſh, white with a yellowiſh border. The ſhell is one inch and a half long and two inches broad.

PLICA. Shell nearly equivalve, with ſix convex ſmoothiſh rays, and ſtriate acroſs. It inhabits India, is about one inch and a quarter long and an inch broad. The ſhell is white, or white ſpotted with brown, or red ſpotted with white; the tranſverſe ſtriæ are placed at a diſtance from each other.

CRENATA. Shell roundiſh with convex rays, the outer ones finely ſtriate longitudinally; margin deeply crenate. The ears are tranſverſely ſtriate.

* SINUOSA. Shell ovate with very numerous and fine ſtriæ; the margin crenate within. It inhabits the Britiſh ſeas; ſhell varied with ſaffron.

SQUAMMOSA. Shell oblong with ſcaly rays, the interſtices broader, and marked with perpendicular ſtriæ. The ſhell is varied with angular lines and ſpots; ears wrinkled perpendicular.

DUBIA. Shell roundiſh, with eighteen rays imbricate with ſcales. The ſhell is nearly half an inch long; ears ſtriate tranſverſely.

* SUBRUFA. Shell with twenty ſmooth rays, the interſtices tranſverſely ſtriate; margin crenate. This is deſcribed and figured in Donovan's Britiſh Shells. It is found on the Britiſh ſhores, and is about two inches long, and two inches broad.

VERSICOLOR. Shell flattened, with eighteen ſmooth rays, the interſtices cancellate. The ſhell is of a pale yellow, white, ſea-green, blackiſh, or red; ears tranſverſely ſtriate.

ROSEA. Shell roundiſh, with five rays. The ſhell is middle-ſized, roſy, with white rays, or green, mixed with yellowiſh, lurid, and leek-green, with livid rays.

FUSCA. Shell brown, with flat rays that diſappear towards the hinge. It inhabits the Indian ſea. The ſhell is white within; lower valve convex, upper valve flat.

TENUIS. Shell thin, flat, purple, with very minute perpendicular ſtriæ croſſing circular tranſverſe ones; within the ſtriæ are elevated.

LUTEA. Shell thin, pale yellow, with thick rays.

MURICATA. Shell roundiſh and white, with a mixture of ſaffron; the rays convex, and very finely and ſharply muricate.

CONSPERSA. Shell roundiſh, tawny, dotted with white and black; the rays are thick.

NODULOSA. Shell roundiſh, brown, with black tranſverſe lines and dots; the rays are convex and knotty.

RADIATA. The ſhell of this ſpecies is thin; the colour is whitiſh-roſy, with white ſtripes; the rays convex.

PUNCTATA. Shell oblong, pale yellow, ſpotted with white; beaks varied with white and brown; the rays are crenate. The ſhell is about two inches long; ears cancellate.

ACULEATA. The ſhell is thin, varied with roſy and whitiſh; in form it is rather roundiſh; the rays are thick, with aculeate ſcales.

PLANA. Shell thin, flat, white, with a ſaffron hinge; the rays are round and broad.

PUSILLA. Shell oblong, red, and very minutely ſtriate.

FLAVESCENS. Shell convex on each ſide, and yellowiſh within; the rays are convex.

FABELLUM. Shell roundiſh, deep red, with a white hinge, and a few ſpots. The rays are ſmooth.

SPONDYLADES. Shell glabrous red; the ears are equal.

VIOLACEA. Shell flattiſh on each ſide, the outſide brown, the inſide violet. It inhabits the Mediterranean.

AURANTIA. Shell roundiſh, plaited, and very finely ſtriate longitudinally, with a white ſemicircular band towards the hinge.

VITTATA. Shell purple within; without with alternate brown and red bands; the rays are convex.

MINIATA. Shell white, with confluent red ſpots; the rays rough; the convex valve with tranſverſe criſp lamellæ. The ſhell of this ſpecies is about an inch and a half long, and the ſame in breadth.

INFLATA. Shell convex on each ſide, cloſed, oblong, pellucid, with thirty-two rays. This is a very rare ſpecies, is ochraceous, thin, and twice as long as it is broad.

b. Ears unequal, one of them generally ciliate, with ſpines within.

Species.

PALLIUM; Ducal Mantle. Shell equivalve, with twelve convex rays; the ſcales are ſtriate, rough, and imbricate. There are two other varieties. They are found in India. The ſhell is ſolid, red, varied with brown and white; ears ſtriate, crenate, or ſcaly, one of them longer; margin of the ſhell denticulate.

SANGUINOLENTA. Shell equivalve, with nine thick obtuſe rays; the interſtices longitudinally ſtriate, tuberculate, prickly. It is found in the Red ſea; reſembles the laſt. The ſhell is white, with ſanguineous ſpots; the margin with crenate plaits, the border purpliſh; ears with tranſverſe nodulous ſtriæ.

MACULOSA. Shell equivalve, pale yellow, with tawny ſpots; twelve rays thick and flattiſh; ears white, with dull ferruginous marks, and tranſverſe ſcaly ribs.

NODOSA. Shell with nine rays, covered with apparently veſicular tubercles. There are three varieties. They inhabit the American and African ocean. The ſhell is ſometimes red or ſcarlet, ſometimes varied with red and white, or tawny and white, mixed with yellow; the upper valve is more convex than the lower; the ear is ſpinous within and beneath.

PES FELIS. Shell with nine ſtriate rough rays; one of the ears very ſmall. It is found on the ſhores of Africa; is ſmall, thin, pellucid, generally pale fleſh-colour, ſpotted and veined; within glabrous white, with ſub ndulate rays and crenate plaits on the margin; the ears with tranſverſe knotty ſtriæ.

PELLUCENS. Shell nearly equivalve, with nine rays, ſmooth, with ſpoon-like hemiſpherical ſcales on the lower valve. It inhabits the African ſeas; is ovate, minute, pellucid, glabrous, white; the upper valve ſpotted with red.

OBLITERATA. Shell ſmooth on the outſide, with twenty-four doubled rays. It inhabits the Indian ocean. The ſhell is marked with very fine decuſſate ſtriæ; the lower valve pale reddiſh and yellowiſh at the hinge; upper valve dirty red or pale tawny.

SANGUINEA. Shell equivalve, with twenty-two rough rays; the ears are ſmall. It inhabits the Mediterranean, Atlantic, and American ſeas. The ſhell is round and flattiſh, red, ſcarlet, or tawny; the ſpaces between the rays are longitudinally ſtriate.

* VARIA.

* Varia. Shell equivalve, with thirty compreſſed rays beſet with tranſverſe prickly ſcales; one ear very ſmall. It is found in moſt European ſeas; varies very much in colour, from pale yellow to various ſhades of orange and brown, with ſometimes a few white ſpots. The ſhell is rather convex, with rough jags or ſpinous protuberances down the rays; ſpaces between the rays not ſtriate; one ear very ſmall, with a double row of ſpines; the other with wrinkled plaits, and armed beneath with from five to ſeven ſpines.

* Pusio. Shell equivalve, with about forty filiform rays, the ſurface often irregular or diſtorted. This is figured in Donovan's Britiſh Shells. It is found in the European, Atlantic, and American ſeas. The ſhell is generally ſmall, and a little longer than it is broad; ſometimes it is ſeen with a ſmooth ſurface, but moſtly with an irregular waved ſurface, as if deformed by an accident: in its colours and marks it is very variable, but commonly it is of a fine red; one of the ears is very ſmall, the other ſharply ſpined beneath.

* Obsoleta. Shell ſmooth, equivalve, ſemitranſparent, dark purple, with eight nearly obſolete rays. Inhabits Britiſh coaſts; three quarters of an inch long. Shell thin, the valves equal and ſhallow, within ſmooth and brown, with a pearly gloſs; outſide dull purpliſh-brown, with numerous longitudinal ſtriæ between the rays; ears very unequal, wrinkled.

Lævis. Shell very ſmooth; ears ribbed. Inhabits Angleſea and Falmouth, is more than half an inch long.

Glabra. Ears nearly or quite equal. Shell equivalve, with from ten to fifteen ſmooth flattiſh rays; the inſide with elevated double ſtriæ. It inhabits the European and American ſeas; nearly two inches long, and as many broad; roundiſh; red, yellow, or brown, ſpotted or clouded, ſometimes white, with the upper valve ſpotted with brown; margin repand.

* Opercularis. Shell with about twenty rays, roundiſh and rough, with decuſſate ſtriæ; the upper valve a little more convex. There is a variety of this ſpecies. It inhabits the Northern ſeas of Europe; and is two inches and a half long and broad. The ſhell is gaping, generally variegated with ſpots and other marks; rays acute, ſometimes rounded; margin repand and toothed within; ears with decuſſate wrinkled ſtriæ, the larger one emarginate and ſpinous under the inciſure. In Devonſhire and Cornwall, where it is found, it is called *frill* or *queen*.

Gibba. Shell equivalve, gibbous, with twenty glabrous rays. It inhabits the American and Atlantic ſeas. The ſhell is convex on each ſide, red, with ſometimes a few white ſpots, and marked with fine crenate longitudinal ſtriæ; margin crenate; ears nearly equal.

Sulcata. Shell white, with fleſh-colour ſpots; the rays glabrous, thirty-two on the lower valve, and twenty-five on the upper. It inhabits the ſhores of Malabar; is about one inch and a half long, and ſomething broader; margin plaited, crenate; lower valve with an emarginate ſpinous ear, upper valve flattened.

Histrionica. Shell thin, flattened, pellucid, with very fine tranſverſe wrinkles, and eleven rays. The ſhell is ſpotted with red, white, and black; rays waved; ears nearly equal.

Islandica. Shell orbicular, with purple circles, and about one hundred rays. It inhabits the Mediterranean, in innumerable varieties. The ſhell is three inches and a half long, and three inches and a quarter broad; ſometimes whitiſh, but moſtly mixed with a fine pale bloom or yellowiſh, and marked with tranſverſe ſemilunar bands; upper valve more elegantly marked, with from fifty to one hundred rays, rough with acute imbricate ſcales; margin crenate; ears with tranſverſe ſcaly ſtriæ, the large one emarginate and ſpinous: the fiſh is eaten.

Triradiata. Shell nearly equivalve, glabrous, immaculate, with very minute ſtriæ. It is found among fuci in the ſeas of Norway. The ſhell is red, with ſmall white ſpots, within reddiſh; upper valve with three rays; ovary of the fiſh yellowiſh.

Fuci. Shell nearly equivalve, ſtriate, ſpotted, rough towards the margin. It inhabits the North ſeas, on the Fucus ſaccharinus. The ſhell is rufous, with whitiſh or paler ſpots, within red, and quite ſmooth, with pellucid ſpots; rays of the upper valve obſolete; ovary of the fiſh rich red.

Tigerina. Shell nearly equivalve, ſtriate, glabrous, red with whitiſh ſpots. It inhabits the North ſeas, on fuci: lower valve more deeply grooved, and varied with large undulate confluent pale yellow ſpots; upper valve dotted; ovary of the fiſh white.

Septemradiata. Shell nearly equivalve, ſtriate, glabrous, with ſeven convex rays. It inhabits the Northern ſeas.

Arata. Shell nearly equivalve, within and without grooved and red; one part rough, the other glabrous. It inhabits the North ſeas.

Senatoria. Shell convex each ſide, with twenty-two rounded and tranſverſe wrinkled rays, the interſtices with longitudinal granulate ſtriæ. It inhabits the Indian ocean; two inches nine lines long, and about as much broad; outſide cheſnut varied with violet and white; inſide violet, the circumference bordered with dull bay.

Citrina. Shell orange, with twenty-two rounded rays and plaited margin; lower valve flatter. It inhabits India; ſome of the rays are ſcaly, and ſome of the grooves have granulate lines.

Turgida. Shell equally convex, both ſides with twenty glabrous rays, the interſtices with tranſverſe crowded wrinkles; the margin with plaited teeth. It is found in the American and Indian ſeas.

Sulphurea. Shell flattened, thin, pellucid, ſtriate, with numerous imbricate rays; the margin with crenate plaits. It inhabits the Red ſea; is two inches long and a little narrower. The ſhell is thin, fragile, of a ſulphur or orange colour, ſometimes red with an orange hinge and a ſemilunar white band, or varied with white and pale tawny, with a ſanguineous border; lower valve with equal rays, thoſe of the upper valve alternately leſs.

Porphyrea. Shell convex, purple, within white or red, with twenty-five thick rounded ſcaly rays. It is found in the Red ſea; two inches three lines long, and as much broad; ſhell varied with a few white ſpots.

Vitrea. Shell hyaline with an acute margin, very ſlender rays, and concentric ſcaly curves. It is found in the North ſeas, among fuci and zoophytes; ſize of a pea; ſhell ſmooth, brittle, white, or varied with white and red; one ear emarginate and ſpinous.

Tranquebaria. Shell with 20 rounded rays, the interſtices very finely wrinkled; margin repand. It inhabits Tranquebar; ſometimes of one colour, which is moſtly orange, ſometimes varied with undulate brown, red, or cinereous ſpots; upper valve more convex.

Saüciata. Shell white, with purple ſpots and numerous unequal rays; the margin crenate. Found in the Red ſea.

Crenulata. Shell oblong, with undulate rays and ſtriæ,

ſtriæ, and tranſverſe interrupted bands; margin crenulate. This is a very ſmall ſpecies.

Innominata. Shell roundiſh, ſpotted, with deep grooves very finely ſtriate tranſverſely; margin crenulate. One of the ears hardly viſible.

Rufescens. Shell roundiſh, pale rufous, with 24 rays; the ears with decuſſate ſtriæ. This ſpecies is of a middle ſize.

Squamata. Shell roundiſh, with thick rays furniſhed with diſtant parallel ſcales, and prickly at the ſides. The ſhell is convex and ſpotted; the margin crenate.

Anonyma. Shell rather oblong, with narrow ſcaly rays, the interſtices broader and ſtriate perpendicularly; ears with perpendicular wrinkles. The ſhell is varied with angular lines and ſpots.

Decemradiata. Shell flattened, with ten ſmooth flat unequal rays; ears tranſverſely ſtriate

Tenuis. Shell thin, with depreſſed ſcaly rays; ears ſhort. It is found in India and the North ſeas. The ſhell is bay, or cinereous ſpotted with black, ſometimes white or carmine, or pale orange.

Valentii. Shell with 20 rays, and tranſverſe ſemilunar bands. It is found in India. The ſhell is red; it reſembles the O maxima, but the ears are unequal.

Media. Shell ſomewhat oblong, with crowded rays. Shell middle-ſized, reddiſh, ſaffron or pieeous.

Crocea. Shell ſaffron, with muricate ſcaly rays alternately leſs.

Florida. Shell roundiſh, white, with roſy ſpots.

Ochroleuca. Shell oblong, ochraceous, with rays ſmooth on one part and granulate on the other.

Mustelina. Shell pale tawny, with yellow ſpots and bands and ſmooth rays; ears tranſverſely ſtriate. The ſhell is $2\frac{1}{4}$ inches long, and about as much broad.

Flammea. Shell ſaffron, rather oblong, with very fine perpendicular ſtriæ.

Incarnata. Shell rather oblong, fleſh-colour, with interrupted red bands and flattened rays. This is ſmall.

Guttata. Shell yellowiſh, rounded, dotted with red, with rays unequally converging at the hinge. It is ſmall.

Depressa. Shell ochraceous, with flat bifid rays. The ſhell is about an inch long, and ſomething broader.

Regia. Shell roundiſh, deep red, with rounded rays. The ear of the lower valve deeply emarginate.

Palliata. Shell equivalve, with numerous ſmooth rays. It reſembles O. pallium, but is leſs rough, and has fewer rays; ſhell ſtraw-colour with purple undulate bands.

Seminuda. Shell orange, oblong, muricate, with ſcales as far as the middle; with 22 rays. The ſhell is $1\frac{3}{4}$ inch long, $1\frac{1}{4}$ broad; ears with very fine ſcales.

Modesta. Shell roundiſh, hoary, with browniſh, reddiſh, and blueiſh ſpots; ſpaces between the rays broad. The ſhell has two filiform bands at the hinge.

Principalis. Shell purple, with a brown margin; the rays ſcaly from the middle and ſmooth at the hinge.

Versicolor. Shell variegated, with pectinate ſmooth rays.

c. Valves more gibbous on one ſide.

Flavicans. Shell nearly equivalve, with eight ſtriate rays, the margin rounded on one ſide. It is found in the South ſeas. The ſhell is rather oblique, white varied with brown and red, within white; the rays yellow; one of the ears very ſhort.

Fasciata. Shell equivalve, with 20 rough rays, the interſtices ſtriate; ears equal, ſmall. Inhabits the American and Atlantic ſeas. The ſhell is white, pellucid, gaping each ſide, very finely ſtriate within; the margin crenate.

Fragilis. Shell equivalve, with 25 rays; margin very entire; ears acute. It inhabits the Nicobar iſlands; reſembles the laſt, but is flatter, and has more rays; ſhell thin, brittle, $1\frac{1}{4}$ inch long, and about half as broad.

Lima. Shell equivalve, with 22 imbricate ſcaly rays, rounded at one margin; ears obliterated. It is found in the Mediterranean, Indian, and Red ſeas. The ſhell three inches long, $2\frac{1}{2}$ broad; white and rather flat; the number of rays uncertain, the ſcales elevated and acute; ears wrinkled.

Glacialis. Shell equivalve, with 50 imbricate interrupted rays; ears equal, one of them unequally plaited. It is found in the American ocean; reſembles the laſt, but has more numerous rays; ſhell ſnowy with a crenate margin; another variety has the margin entire.

Hians. Shell whitiſh, thin, gaping each ſide and oblique, with obſolete undulate rays, and tranſverſe rounded ſemilunar ſtriæ. Inhabits Norway; $1\frac{1}{2}$ inch long, $\frac{3}{4}$ of an inch broad; ears very ſmall and acute; margin crenate, very entire within.

Excavata. Shell dirty-white, with longitudinal undulate ſtriæ, and a few tranſverſe rings, ſmooth within; one ear obſolete; margin very entire. It is found in Norway, but is rare; five inches long, $3\frac{1}{4}$ board.

B. *Rough and generally plaited on the outſide.* Oyſters.

Malleus. Shell equivalve, three-lobed, two of the lobes placed tranſverſely like the head of a hammer. This ſpecies is found in the deep parts of the Indian and South ſeas, and is very rare. Shell about ſix inches long and $4\frac{3}{4}$ broad; black with a dark blue caſt, gaping, formed like a croſs; the valves lamellate.

Valsella. Shell ſubpellucid, narrow, elongated, brittle, lamellate; one end rounded; within very ſmooth and gloſſy. It inhabits the Red ſea; $3\frac{1}{2}$ inches long, one broad. The ſhell is violet, tawny, or ferruginous, gaping at the hinge; rough on the outſide, and thinner at the rounded end.

Anatina. Shell pellucid, lamellate, and laterally incurved. It inhabits the Nicobar iſlands; about an inch broad, and including the curvature three inches long; its ſhape in ſome meaſure reſembles a duck when ſitting; ſhell thin, brittle, varied with white and violet.

Diluviana. Shell plaited on the outſide; the margin with erect acutangular teeth. This is found in a foſſile ſtate in the calcareous mountains of Sweden, about the ſize of a common oyſter; the margin with erect ſerratures, formed as it were of the imbricate lamellæ of the ſhell, and tranſverſely ſtriate; valves with pectinate plaits and acute wrinkles.

Folium. Shell ovate, obtuſely plaited at the ſides, paraſitical. It inhabits the Indian ocean, where it is frequently found adhering to Gorgonia; ſhell ſtraw-colour, pale tawny, or violet, within ſilvery; hinge with a triangular hollow; upper valve turgid on the back towards the middle, wrinkled each ſide and tranſverſely ribbed; lower valve leſs flatter and grooved in the middle.

Orbicularis. Shell orbicular, flat, with an entire crenate margin. Shell with a very obtuſe margin, about the ſize of the end joint of the thumb.

* Edulis, or the common oyſter. The ſhell of this well-known and highly eſteemed ſpecies is nearly orbicular and rugged, with undulate imbricate ſcales; one valve is flat and very entire. There are ſix varieties of this ſpecies, found in different parts of the European and Indian ſeas, affixed to rocks, or in large beds. The ſhell is of various ſizes, forms, and colours, within white, and often gloſſy like mother-of-pearl.

pearl. The old ſhells have frequently an ANOMIA (which ſee) fixed to them, and are ſometimes covered with ſerpulæ, lepades, fertulariæ, and other marine productions. The oyſter is ſuppoſed by naturaliſts to be an hermaphrodite animal. The ſpawn which they caſt in May adheres to the rocks, and other ſubſtances at the bottom of the ſea, and the ſhell is ſaid to be formed in the ſpace of 24 hours. It was formerly thought to have no power of locomotion, but it is now aſcertained, by accurate obſervation, that it can move from place to place, and vary its habits according to circumſtances. Oyſters which are recently taken up from places that are left dry by the ſea open their ſhell, loſe their water, and die in a few days; but if kept in reſervoirs, in which they are left occaſionally by the ſea, expoſed to the rays of the ſun, to ſevere cold, or are diſturbed in their beds, acquire the habit of keeping the ſhell cloſe when they are uncovered with water, and exiſt without injury for a long time. Mud and ſea-weeds are extremely injurious to the propagation and increaſe of the oyſter. Other ſhell-fiſh, and cruſtaceous animals, as muſcles, ſcallops, ſtar-fiſh, and crabs, are their moſt deſtructive enemies.

Oyſters are of different colours in different places; in Spain they are found of a red and ruſſet colour; in Illyria they are brown, but the fiſh is black, and in the Red ſea of the colour of the rainbow. The green oyſter, which is eaten in Paris, is brought from Dieppe. The oyſters from Britanny have been long famous, but thoſe which are brought from Merennes in Saintonge, are in the higheſt eſtimation. In tropical regions, the common oyſter is found attached to trees; this aſſertion has been frequently ranked among groundleſs and fabulous traditions, but the fact is eaſily explained. In warm climates, where vegetation is very luxuriant, a great variety of plants, among which are large trees, grow on the ſhores at the very edge of the ſea; and particularly on thoſe places which are ſheltered from the agitation of the waves. In ſuch places as the heads of bays and harbours, great abundance of mangrove trees grow up from the bottom, where it is ſeveral feet deep, covered with water. It is generally on the mangrove tree that the oyſter is found in the Weſt Indies. Without the trouble of picking them from the trees, the branches growing under water, to which they are attached, are cut off, carried home in baſkets, and in this ſtate brought to table, where they are eaten raw or roaſted.

Britain has long been noted for its oyſters; and the ancient Romans, who were extremely fond of this fiſh, had their layers or ſtews for oyſters as we have at preſent. Sergius Orata was the inventor of them, as early as the time of Lucius Craſſus the orator. He did not, however, conſtruct them for the purpoſe of indulging his appetite, but for the ſake of the profit attached to them. This country ſtill retains its ſuperiority in oyſters over other countries. Moſt of our coaſts produce them naturally, and in ſuch places they are taken by DREDGING, (which ſee,) and are a conſiderable article of commerce, in the raw and pickled ſtate. Stews or layers of oyſters are formed in places which nature never allotted as habitations for them. Thoſe near Colcheſter have long been famous. The oyſters or ſpats are brought to convenient places, where they improve in taſte and ſize. See MILTON.

SEMIAURATA. Shell oval, ſlightly eared, ſmooth, with an oblique baſe. It inhabits the Mediterranean, is about 1½ inch long, and 1¼ broad; of a dirty olive, with a few undulate white lines; very thin; each valve convex and ending in a beak; hinge with five rounded hollows.

* STRIATA. Shell oval, with longitudinal filiform ridges; inſide green. It is found in European ſeas, and is about an inch in diameter. The ſhell is thick, ſtrong, nearly opaque, not membranous, as in the common oyſter, with numerous ſlender irregular ridges, divided towards the bottom; upper valve flattiſh, lower concave; hinge broad, deep, ſomewhat triangular and ſtriate tranſverſely. In many ſhells is a white radiate mark below the hinge, formed by the cartilage of the fiſh.

FORNICATA. Shell rough, oblong, linear, with divergent hinges, vaulted internally. It is found in the Red ſea. The ſhell is brittle, membranaceous, tawny, about as long as a finger, terminating at the hinge in an elongated acutangular beak.

SINENSIS. Shell rough, lamellate, unequal, and glabrous within; lower valve larger, concave, and ending in a beak, with ten obtuſe plaits. It is found on the Chineſe ſhores; four inches long, and a little narrowed; ſhell ruſſet-brown, within whitiſh towards the hinge.

SPONDILOIDEA. Shell equivalve, pellucid, flattened, oval, beaked, glabrous, with perpendicular, undulate, granulate ſtriæ on the upper valve; margin very ſharp. Inhabits India: three inches two lines long, two inches five lines broad; ſhell white, with a few tawny ſpots.

FORSKAHLII. Shell plaited, and terminating in a long incurved hollow beak; the middle ribs with imbricate ſpinous wrinkles; the other valve flat. It is found in the Red ſea. Two inches three lines long, and about an inch broad; the flat valve whitiſh, the other nearly violet.

PLICATULA. Shell with longitudinal wrinkled plaits; the lower valve a little leſs and flatter. It inhabits the American and Mediterranean ſeas. Varies very much in ſhape and ſize; but is generally cinereous, with a mixture of violet, ſometimes white, with red or blueiſh ſtreaks.

ROSTRATA. Shell oblong, rugged; the upper valve lamellate, with a denticulate margin, the other excavated and longitudinally grooved; beak prominent. It inhabits the Mediterranean; upper valve yellowiſh-green, the other violet, varied with white; within cretaceous or chalky-white.

VIRGINICA. Shell nearly equivalve, thick, rough, lamellous; one valve with a prominent beak. It is found in the American and Indian ocean; nine inches long and four broad; whitiſh or ochraceous, within gloſſy-white.

CORNUCOPIÆ. Upper valve flat, lower one hollow and ſtriate, rough with ſcales, wrinkles and plaits, and ending in an elongated beak. It is found in the Indian and African oceans.

PARASITICA. Shell thin; lower valve convex and thicker, the other flat. It inhabits the Indian and Atlantic ſeas, and fixes itſelf to the roots and ſtumps of trees growing cloſe to and hanging over the water, eſpecially the *Mangifera;* varies in form and ſize, but is often as large as the palm of the hand.

EXALBIDA. Shell thin, the upper valve longer and more convex. This is found in the Adriatic, fixed to other ſhells, ſometimes alone, ſometimes ſeveral together; about one inch and a half long, but is variable as to ſhape and ſize; generally whitiſh, rarely yellow or violet.

CRISTATA. Shell rugged, with imbricate lamellæ; the margin with obtuſely plaited teeth; the beak of one valve produced. Shell an inch long, and ten lines broad, white, with a few black ſpots; hinge with a broad conic tooth in the middle.

SENEGALENSIS. Shell equivalve, roundiſh, ſmooth, flat. It inhabits the ſhores of Senegal, and adheres to rocks; about two inches in diameter; tawny, within whitiſh.

STELLATA. Shell thin, depreſſed, rough, unequal; the upper valve ribbed, the ribs with a few ſpines. It is found in Guinea ſometimes affixed to other bodies by the hinge; ſometimes

ſometimes round, ſometimes oblong; very thin, white, with red or blueiſh rays, ſpots, or marks.

Ovalis. Shell oval, very thin, and terminating in a ſhort acute lateral channelled beak; with obſolete, unequal, perpendicular ſtriæ. The ſhell is about an inch long, brittle, whitiſh, within gloſſy ſilver-white; lower valve exceeding the upper both in length and breadth.

Papyracea. Shell roundiſh, ſnowy, very thin, pellucid; upper valve terminating in a ſhort acute beak. It is found firmly fixed with the Lepas tintinnabulum.

Annulata. Shell equivalve, orbicular, white, with concentric ſemicircles. It is found in the North ſeas.

Retusa. Shell equivalve, oblong, white, glabrous, ſtriate; with an umbo or knob remote from the hinge. This is alſo found in the North ſeas.

C. *Hinge with a perpendicular grooved line.*

Perna. Shell equivalve, obovate, unequal, rounder at one end.

Isognomum. Shell equivalve, with a larger lobe, nearly forming a right angle with the hinge. There are four varieties of this ſpecies. They are found in the Indian ocean and South ſeas; from five to ſix inches long, and about one inch and three quarters broad in the middle; ſhell black, with a violet mixture, and pearly within; lamellate, with an open beak; a very rare ſhell.

Ephippium. Shell equivalve, orbicular, compreſſed, membranaceous. Found in the Indian ocean and Cape of Good Hope; very rare. The ſhell is about five inches long, five and a half broad, blackiſh, furruginous or purpliſh, and pearly within; roundiſh, lamellate, with a very acute margin.

Picta. Shell equivalve, thin, pellucid, and pointed at the hinge, the other end dilated; margin very acute. It inhabits the Red ſea; is more than an inch broad, and above two long; yellowiſh-brown, with paler undulate rays.

Legumen. Shell flat, hoary, thin, pellucid, lamellate; hinge with an oblique line; the interſtices of the grooves black. This ſpecies inhabits the Nicobar iſlands; is four lines broad, and above two inches long; near the knob is a livid ſpot.

Alata. Shell flat, brittle, pellucid, and dilated towards the margin; hinge with an oblique line ending in a ſmall beak. It is found in America.

Mytiloides. Shell nearly equivalve, ovate, ventricoſe, ſtraight. It is found in a foſſile ſtate in Alſace.

Torta. Shell equivalve, intorted. This alſo is found foſſile in Alſace.

Pes-lutræ. Shell equivalve, ſmooth, wedge-ſhaped, with ſix obtuſe plaits. Shell varied with purpliſh and white, and marked with very fine longitudinal ſtriæ; the margin ſlightly ſcalloped.

OSTRICH, in *Ornithology*. See Struthio.

OSTRICONI, in *Geography*, a town of the iſland of Corſica, near a river of the ſame name, which runs into the ſea; 22 miles W.S.W. of Baſtia.

OSTRITZ, or Wotrow, a town of Upper Luſatia, on the Neiſſe; 7 miles S. of Gorlitz. N. lat. 51° 1′. E. long. 15° 1′.

OSTROCOL, a town of Pruſſia, in Natangen; 9 miles S.S.E. of Lick.

OSTROG, a town of Poland, in Volhynia, once the capital of a duchy, ceded to Poland in 1609; 38 miles N.N.W. of Conſtantinov.

OSTROGOTHIA. See Gothland.

OSTROGOTHS, or Eastern Goths, in *Ancient Hiſtory*, a denomination given to thoſe Goths, who, before they left Scandinavia, inhabited the more eaſtern parts near the Baltic, in contradiſtinction to the Weſtrogoths, or Weſtern Goths, who inhabited that part of Scandinavia which borders on Denmark. The name was afterwards appropriated to thoſe Goths who eſtabliſhed themſelves on the other ſide of the Danube, and thus they were diſtinguiſhed from thoſe who proceeded farther weſtward and into Pannonia. The emperor Marcian, about A.D. 453, granted to the Oſtrogoths the whole of Pannonia from Sirmium, now Scriniſh, in Sclavonia, to Vindobona, now Vienna, in Auſtria. They, as well as the other barbarians, acknowledged the authority of the Conſtantinopolitan emperor, and were ſubjects of the empire; but at the ſame time governed by their own princes, to whom the emperor agreed to pay an annual penſion, upon their promiſing to guard the frontiers of the empire, and ſerve, when wanted, in the Roman armies. Pannonia being granted to the Oſtrogoths, the three brothers, who had previouſly reigned jointly, agreed to divide that country between them, Valemir ſettling in the eaſtern part of it, Theodomir in the weſtern, and Videmir between the other two. They were ſcarcely eſtabliſhed in their new territories, when the ſons of Attila, purſuing them even into Pannonia, fell upon Valemir in the vicinity of Sirmium; but that prince, with a ſmall number of men, defeated them with great ſlaughter, and obliged them to take refuge in that part of Scythia, which bordered on the Danube. About eight years after, the Goths being engaged in a war with the Satagæ, one of Attila's ſons, availing himſelf of that opportunity, entered Pannonia at the head of a conſiderable army, having ravaged the country; but the Goths, leaving the Satagæ, marched with all their forces againſt the Huns, who received ſuch a repulſe in their onſet, that they ever after ſtood in awe of the Goths, and never offered to moleſt them.

In the year 455, the emperor Leo, refuſing, under various pretences, to pay the Oſtrogoths their uſual penſion, they entered Illyricum, and there committed dreadful ravages; but Anthemius, the ſon-in-law of the emperor Marcian, obliged them to retire with conſiderable loſs. At length Leo renewed with them ancient treaties, and reeſtabliſhed peace, upon the emperor's promiſing to pay the Goths their arrears, and for the future 300 pounds weight of gold annually. On the other hand, Valemir ſent to Conſtantinople, by way of hoſtage, the famous Theodoric, afterwards king of Italy, then only eight years old. Leo received him with reſpect, maintained him at his court for ten years, in a manner ſuitable to his rank, and had him inſtructed by the beſt maſters in every branch of polite literature. In the tenth year of Leo's reign a war broke out between the Goths in Pannonia and the Squiri, who had been permitted by Marcian to ſettle in Leſſer Scythia and Lower Mœſia. Leo took part with the Squiri, who were nevertheleſs utterly defeated. The Squiri obtaining aſſiſtance, renewed the war, and laid waſte the territories of the Goths to a great extent. The Goths, putting themſelves under the command of the two ſurviving brothers, Theodomir and Videmir, Valemir having been previouſly ſlain in battle, and engaging the enemy on the banks of the Danube, ſlew a great number, and obliged the reſt to retire beyond that river. Theodomir having gained great ſucceſs in this conteſt, received, on his return, his ſon Theodoric, whom Leo had ſent back with rich preſents, after having kept him as a hoſtage for ten years. Theodoric had immediately recourſe to arms, and ſlew the king of the Sarmatians. The Goths in Pannonia determined to make war on the empire. On this occaſion part of the Oſtrogoths joined the Viſigoths in Gaul, and aſſiſted them in the conqueſt of that country, and in the reduction of Spain, becoming one people with them.

Theodomir entered Illyricum, and with the co-operation of his ſon Theodoric reduced ſeveral cities. Soon after this event a peace was concluded between the Romans and the Goths. Upon the death of Theodomir, his ſon Theodoric ſucceeded him; and declared for the emperor Zeno againſt the uſurper Baſiliſcus. Zeno, however, abandoned him, and Theodoric ravaged Thrace and Macedon. Theodoric afterwards marched into Italy, and A.D. 489, put Odoacer, who had aſſumed the title of king of Italy, after having put Oreſtes to death and depoſed his ſon Auguſtulus, to flight in two ſucceſſive engagements. Circumſtances, however, proving unfavourable, Theodoric had recourſe to Alaric, king of the Viſigoths, who had ſettled in Gaul. As the Viſigoths and Oſtrogoths were originally the ſame nation, and the Viſigoths had received among them, about ſixteen years before, a great number of Oſtrogoths, they readily granted him the deſired ſupplies; and accordingly he proceeded to beſiege Odoacer in Ravenna; and at length reduced all Italy. Having put Odoacer to death, Theodoric was proclaimed by the Goths and acknowledged by the emperor Anaſtaſius, who had ſucceeded Zeno, king of Italy. (See the biographical article THEODORIC.) Thus the kingdom of the Oſtrogoths was eſtabliſhed in Italy.

OSTROGOZK, in *Geography*, a town of Ruſſia, in the government of Voronez; 40 miles S. of Voronez. N. lat. 51°. E. long. 38° 4′.

OSTROGZEK, a town of Poland, in Volhynia; 18 miles S.W. of Berdiczow.

OSTROKOLLA, a town of Pruſſia; 80 miles S.E. of Konigſberg.

OSTROLENKA, a town of the duchy of Warſaw; 48 miles N.E. of Warſaw.

OSTROMETKE, a town of Pruſſia, in the palatinate of Culm; 10 miles S. of Culm.

OSTROPOLE, a town of Poland, in Volhynia; 10 miles N.E. of Conſtantinov.

OSTROSINA, a town of Croatia; 12 miles S.E. of Carlſtadt.

OSTROV, a town of Ruſſia, in the government of Pſkov, on the river Velika. N. lat. 57° 20′. E. long. 28° 14′.

OSTROUCHOVSKAIA, a town of Ruſſia, in the country of the Coſſacks, on the Choper; 44 miles W.S.W. of Arkadinſkaia.

OSTROVITZ, a town of Croatia; 12 miles S. of Bihacs.

OSTROVIZZA, a town and fortreſs of Dalmatia, which was taken by Soliman, in 1520, and ſoon after reſtored to the Venetians; its fortifications are deſtroyed; 14 miles N. of Scardona.

OSTROVNOE, a lake of Ruſſia, in the government of Kolivan; 120 miles S. of Kolivan. N. lat. 52° 24′. E. long. 80° 24′.

OSTROVSKOI, a town of Ruſſia, in the government of Koſtrom; 48 miles E.N.E. of Vetluga.

OSTROW, a town of the duchy of Warſaw; 60 miles E.N.E. of Warſaw.—Alſo, a town of Poland, in Volhynia; 22 miles S. of Lucko.—Alſo, a town of Lithuania, in the palatinate of Novogrodek; 44 miles S. of Novogrodek.

OSTROWIEC, a town of Lithuania, in the palatinate of Wilna; three miles E. of Wilna.

OSTROZECK, a town of Poland, in Volhynia; 42 miles W.N.W. of Zytomiers.

OSTRYA, or OSTRYS, in *Botany*, ὀστρυς of Theophraſtus, is by ſome taken for the Lilac, *Syringa vulgaris*; but the deſcription of that ancient writer far better accords with the Hornbeam, *Carpinus Betulus*, which therefore is uſually taken for his ὀστρυς. The "thick fibres, folds, and ſerratures" of the leaf, are characteriſtic of the latter, not of the former. Linnæus retains the name as a ſpecific appellation for the Italian, or Hop, Hornbeam, (ſee CARPINUS, ſp. 4.) which is ſo remarkable for its white, inflated, hop-like fruit.

OSTRYNIA, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 20 miles W.S.W. of Lidda.

OSTUALLA, a town of Norway; 50 miles N. of Frederickſtadt.

OSTUNI, a town of Naples, in the province of Otranto, the ſee of a biſhop, ſuffragan of Brindiſi, containing two churches and five monaſteries; 51 miles N.W. of Otranto. N. lat. 40° 59′. E. long. 17° 38′.

OSUNA, a town of Spain, in the province of Seville; 12 miles S.S.W. of Ecija.

OSUNPOUR, a town of Hindooſtan, in Bengal; 45 miles N.N E. of Dacca. N. lat. 24° 25′. E. long. 90° 48′.

OSWALD, in *Biography*, king of Northumberland, was obliged, after the death of Ethelfrid, his father, to take refuge in Ireland, his uncle Edwin having taken poſſeſſion of the throne. In his retreat he became a Chriſtian, and returning to his own country, defeated Cerdowalla, or Cædwalla, king of the Britons, who loſt his life in the conteſt. This was the laſt vigorous effort which the Britons made againſt the Saxons. Oſwald re-united the two kingdoms of Northumberland, but was ſlain in battle againſt Penda. king of Mercia, A.D. 643. Oſwald is much celebrated for his ſanctity and charity by monkiſh hiſtorians; and they pretend that his reliques wrought miracles, particularly in the cure of a ſick horſe, which had approached the place of his interment. Hume.

OSWALD, ERASMUS, a learned German, profeſſor of the mathematics and of the Hebrew language, was born in the county of Merckenſtein, in Auſtria, in the year 1511. Having gone through a courſe of grammar learning, he ſtudied ſucceſſively at the univerſities of Ingoldſtat, Leipſic, and Baſil, and in the laſt named place he diſtinguiſhed himſelf by his proficiency in the mathematical ſciences and the Hebrew tongue, under the inſtructions of the celebrated Sebaſtian Munſter. From Baſil he went to Memmingen, in Swabia, on an invitation from the magiſtrates to become mathematical profeſſor in that city; and afterwards he went to Tubingen, and was elected profeſſor of Hebrew. In imitation of Sebaſtian Munſter, he did not confine his inſtructions to the Hebrew language only, but delivered a courſe of lectures in the mathematics. In 1552 he accepted of the united profeſſorſhips of mathematics and Hebrew at Friburg, which he held for more than twenty-ſeven years. He died in 1579, in the ſixty-ninth year of his age. He was author of "Commentaria in Theorias Planetarum;" "De primo mobili;" "Commentaria in Sphæram Joannis de Sacroboſco;" "In Almageſtum Ptolomæi Annotationes;" "Gentium Kalendarium;" "Oratio funebris de Obitu Sebaſtiani Munſterii," written in the Hebrew language. He likewiſe tranſlated the New Teſtament into Hebrew, an undertaking on which no perſon had ventured before his time. He was author of paraphraſes on ſeveral books of the bible, and other works.

OSWALD, in *Geography*, a ſmall iſland in the gulf of Florida, near the coaſt of Eaſt Florida. N. lat. 25° 48′. W. long. 80° 22′.

OSWALD, *St.*, a town of Auſtria; 5 miles N. of Roſbach.—Alſo, a town of the duchy of Stiria; 11 miles N.E. of Windiſch Gratz.—Alſo, a town of Auſtria; 8 miles S.W. of Neuſtatt.—Alſo, a town of the duchy of Stiria; 6 miles S. of

O S W

S. of Landſperg.—Alſo, a town of Auſtria; 5 miles E. of Freyſtatt.—Alſo, a town of Upper Carniola; 11 miles E. of Stein.

OSWANSIO, a town of Sweden, in Geſtricia; 17 miles W.S.W. of Geffle.

OSWEGATCHIE, a river of North America, which runs a north-weſterly courſe from its ſource into St. Lawrence county, New York; after ſome windings it purſues a weſterly courſe by the northern part of a lake of its name, the waters of which it receives, and then runs ſeven miles N.W. into the St. Lawrence. The lake of this name is about 18 miles long from S.W. to N.E., and ſends its waters north-weſtward into the river of its name. It is about ten miles N.E. of the Thouſand lakes, near the entrance into lake Ontario.

OSWEGATCHIES, an Indian tribe reſiding at Swagatchey, on the river St. Lawrence, in Canada. Thirty years ago they could furniſh about 100 warriors.

OSWEGO, a navigable river of New York, which conveys the waters of Oneida, and a number of ſmall lakes, into lake Ontario. It is more commonly called *Onondago*.—Alſo, a fortreſs on the eaſt ſide of the mouth of the above river, and S.E. ſide of lake Ontario. N. lat. 43° 20′. W. long. 75° 43′. It was taken by the Britiſh from the French in 1756, and confirmed to them by the peace of 1763. It was delivered up to the United States July 14, 1766. It is about 150 or 160 miles E. by N. of Niagara. N. lat. 44° 43′. W. long. 76° 50′.

Oswego *Creek, Great*, lies in the county of Lincoln, Upper Canada, and runs into the river Welland, above the Little Oſwego creek, near the N.W. part of the townſhip of Wainfleet.

Oswego *Tea*, in *Botany*. See Monarda.

OSWESTRY, in *Geography*, a borough, market-town, and pariſh, in the hundred of Oſweſtry, and county of Salop, England, is ſituated on the great road from London to Holyhead, at the diſtance of 18 miles from Shrewſbury, and 179½ from the metropolis. The town ſtands upon higher ground than any other in Shropſhire, and the country around is delightfully varied with hills, vales, wood, and water, and exhibits ſome very rich and pictureſque ſcenery. It is a borough by preſcription, and is governed by a mayor, recorder, high ſteward, town-clerk, murenger, coroner, and other inferior officers. The body corporate conſiſts of the mayor, twelve aldermen, and fifteen common councilmen, who elect the mayor, recorder, and murenger; but the high ſteward and town-clerk are nominated by the lord of the manor, and the office of coroner is always held by the chief magiſtrate of the preceding year. The petty ſeſſions for the hundred are holden here, beſides the courts connected with the borough. Wedneſday and Saturday of every week are the market-days in this town, and there are ſix fairs annually. Here is an excellent free grammar-ſchool, of recent erection. The church is a very ſpacious building, with a plain, well proportioned tower at one end. Oſweſtry has been much improved within the laſt two years, in conſequence of an act obtained, in 1810, for widening, paving, and lighting the ſtreets, and of the ſpirit of building which has reſulted from that meaſure. According to the parliament returns of 1811, the houſes in the town were 788, and the inhabitants 3479, in number.

Oſweſtry is a town of great antiquity. The Saxons called it Maeſerfield, or Macerfelth, ſignifying the acornfield; and the Britons Tre-eveſan-gludddiu in Urbern, Tre-Kadari, or the town of Great Oaks. Its preſent appellation, which is a corruption for Oſwaldſtre, was derived from the name of St. Oſwald, king of Northumberland, who was defeated and ſlain here by Penda, king of Mercia, one of the moſt cruel and bloody tyrants that ever diſgraced a throne. Subſequently, when the great Offa conſtructed the barrier ſtill known by his name, Oſweſtry ſtood between it and Watt's-dyke, which ran parallel to the former, at the diſtance of two miles. It was thus rendered a border-town, and hence was frequently the ſcene of conteſt, firſt between the Saxons and the Britons, and afterwards between the latter and the Normans. Henry II. lay here previous to his defeat by the Welſh on the Berwin mountains. In 1212 king John burnt both the town and caſtle, which were then in the poſſeſſion of the Fitz-Alans, and plundered a part of Wales, on account of the refuſal of Llewellin to join his ſtandard, in oppoſition to Lewis, the dauphin of France, who had been invited to England by the rebellious barons. Oſweſtry was likewiſe deſtroyed by the Welſh prince, called Llewellin the Great, in 1233. During this period it was encircled by a ſtrong wall, which had four gates fronting the four cardinal points. Some traces of the wall ſtill remain, but the gates were entirely demoliſhed about the year 1769. Of the caſtle, which ſtood on a high, artificial mount at the weſt ſide of the town, only a few fragments now exiſt. Theſe, however, are ſufficient to indicate its former prodigious ſtrength, and conſequent importance, as a place of defence.

South from Oſweſtry is ſituated the elegant manſion of Aſton-park, the property of W. Lloyd, eſq.; and near the village of Weſt-Felton, in this neighbourhood, is the villa of John F. M. Dovaſton, eſq. called "The Nurſery." This gentleman has, within theſe few months, publiſhed a volume of poems, which may juſtly entitle him to hold a high rank among the poets of the age. His father, though he never appeared as an author, was a man of ſingular genius, and has left a large collection of MSS on the ſubject of antiquities, now in the poſſeſſion of his ſon, together with a variety of philoſophical and muſical inſtruments conſtructed by his own hands, and upon new principles. About a quarter of a mile north-eaſt from Oſweſtry is an ancient fortification called Old-Fort, which the Welſh formerly denominated Llys-Ogran, or Caer-Ogran, that is, Ogran's palace, or ſtrong-hold. It conſiſts of three deep entrenchments, encircling a natural eminence, having a ſudden aſcent on all ſides. Beyond this ſtand the venerable ruins of Whittingham-caſtle, which was built more than a century before the conqueſt, and after that event became a baronial reſidence of the Montgomeries, the Peverells, and the Fitz-guarines. The ſituation of this caſtle is extremely pictureſque; its eaſtern walls being waſhed by a fine lake, ſhaded with large, old oaks, and having a ſmall iſlet in its centre, covered with tall Wych-elms and aſh-trees. Knockin-caſtle, about five miles from Oſweſtry, was built by lord L'Eſtrange, or Strange, and continued in the poſſeſſion of his family till the reign of Edward IV., when it paſſed into the family of the Stanlies, earls of Derby. The village here had formerly a weekly market, and fairs, and was a place of conſiderable importance. Chirk-caſtle, on the confines of Denbighſhire, ſtands on the ſcite of a more ancient fortreſs, called Caſtell-Crogen, which was demoliſhed in the reign of Edward I., and the preſent ſtructure erected in its ſtead, by Roger Mortimer. In the time of the civil wars between king Charles and his parliament, this caſtle was the property of ſir Thomas Middleton, the celebrated parliamentary general, whoſe deſcendants, by the female line, ſtill poſſeſs it. It is a ſquare building, ſtrengthened at the angles by maſſy baſtion-like towers, and having a court in the centre. A

picture gallery in this edifice contains a large collection of portraits. Beauties of England and Wales, vol. xiii. by J. Nightingale and R. Rylance, and vol. xvii. by J. Evans.

OSWIECZIN, a town of Poland, in the palatinate of Cracow, on the Viſtula; 32 miles W. of Cracow.

OSYMANDYAS, in *Biography*, an Egyptian king, and the firſt monarch who formed a library, cauſed a coloſſal ſtatue of himſelf to be erected, on which was this inſcription; "I am Oſymandyas, king of kings; whoever will diſpute this title with me, let him ſurpaſs my works." Moreri.

OSYRIS, in *Botany*, ὀσυρις of Dioſcorides, which he deſcribes as "a ſmall ſhrub, with numerous, dark, tough branches;" ſo that profeſſor Martyn's conjectural derivation of the name from ὄζος, *a branch*, is very probably juſt. Some take *Antirrhinum Linaria* for the true *Oſyris*.—Linn. Gen. 515. Schreb. 677. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 394. Juſſ. 75. Lamarck Illuſtr. t. 802. (Caſia; Tourn. t. 488.)—Claſs and order, *Dioecia Triandria*. Nat. Ord. *Calyciflorae*, Linn. *Elaeagni*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, turbinate, in three equal, ovate, acute, ſpreading ſegments. *Cor.* none, except a three-fold, marginal, nectariferous gland. *Stam.* Filaments three, very ſhort, inſerted into the calyx; anthers roundiſh, ſmall. *Piſt.* an abortive rudiment.

Female, *Cal.* ſhaped like that of the male, ſuperior, permanent, very ſmall. *Cor.* none, as in the male. *Stam.* as in the male, but abortive. *Piſt.* Germen turbinate, inferior; ſtyle the length of the ſtamens; ſtigma in three deep ſpreading ſegments. *Peric.* Drupa globoſe, umbilicated, of one cell. *Seed.* Nut globoſe, filling the cavity of the pericarp.

Eſſ. Ch. Male, Calyx three-cleft. Corolla none.

Female, Calyx three-cleft. Corolla none. Stigma in three deep ſegments. Drupa umbilicated, of one cell. Nut globoſe.

1. O. *alba*. Poet's Caſia, or Gardrobe. Linn. Sp. Pl. 1450. Scop. Carn. v. 2. 260. (Caſia poetica monſpelienſium; Camer. Epit. 26. C. poetica Lobelii; Ger. em. 1293.)—Leaves linear-obovate. Flower-ſtalks axillary.—Native of the ſouth of Europe. It has been brought into our greenhouſes, but having nothing to recommend it, and ſcarcely ever flowering, is now hardly to be met with. The *ſtem* is ſhrubby, much branched, angular, hard and rigid, with the aſpect of ſome kind of broom. *Leaves* alternate, an inch long, obovate, very narrow, entire, ſmooth, evergreen, rather glaucous. *Flowers* ſmall, greeniſh, on ſhort, ſimple, axillary ſtalks. *Fruit* ſcarlet, the ſize of a currant.

Scopoli would unite under this genus the *Elaeagnus* and *Hippophae* of Linnæus, to which he was led by theoretical principles, without regard to nature, or to genuine rules of ſyſtematic arrangement.

2. O. *japonica*. Japaneſe Oſyris. Thunb. Jap. 31. Murray in Linn. Syſt. Veg. ed. 14. 881.—Leaves ovate. Flower-ſtalks from the rib of the leaf. Native of mountains in Japan. *Stem* ſhrubby, ſix feet high, with ſmooth, flexible, round *branches*. *Leaves* alternate, abundant about the tops of the branches, ſtalked, ovate, pointed, with briſtly ſerratures, ribbed, ſmooth on both ſides, unequal, an inch long or more. *Flower-ſtalks* about eight, collected into an umbel, from the midrib of the leaf, a line in length. *Fruit* unknown, ſo that Thunberg was uncertain as to the genus; yet he did not conceive that he had materials ſufficient to eſtabliſh a new one. The ſerrated *leaves* are remarkable, conſidering the other characters, or one might ſuſpect this plant to be partly allied to the *Aſparagi*.

OSYRIS, in *Gardening*, contains a plant of the ſhrubby kind, of which the ſpecies cultivated is, the poet's caſia, (O. alba).

Method of Culture.—Theſe plants are increaſed, by ſowing the berries in autumn, as ſoon as ripe, in ſome gravelly, ſtony, or ſimilar ſituation, on the ſide of a riſing ground, either in the places where the plants are to remain, which is the moſt ſucceſsful, or in a nurſery-bed for tranſplanting. As the ſeeds often remain two years before they vegetate, the places ſhould be kept clear from weeds during that time, or till the plants appear. They afterwards require only to be freed from weeds.

They afford variety in beds, borders, or other places, by the beauty of their fruit.

OSZMIANA, Oscкmiana, or *Oſmiana*, in *Geography*, a town of Lithuania, in the palatinate of Wilna, the principal place of a diſtrict, where provincial diets and juſtice-courts are held; 28 miles S.E. of Wilna.

OTABALO, a juriſdiction of South America, in the province of Quito, connected on the S. with that of San Miguel de Ibarra. The lands are laid out in plantations, and produce great quantities of ſugar. The Indians in the villages, and alſo thoſe who are independent, manufacture great variety of cottons, *viz.* carpets, pavilions for beds, quilts in damaſk work, wholly of cotton, either white, blue, or variegated with different colours; all which are highly valued in the provinces of Quito and Peru, where they are diſpoſed of to great advantage. The wheat and barley are ſown here, like Indian corn, in little holes, a foot diſtant from each other, into each of which are dropped five or ſix grains; and they generally reap above a hundred-fold. This juriſdiction abounds with horſes and black cattle; and from the milk of the latter large quantities of cheeſe are made. The fertility of the country is very much promoted by a great number of rivulets. Its flocks of ſheep are alſo numerous, though they ſeem to be neglected by the inhabitants. The principal place in this juriſdiction is Otabalo, which is ſo large and populous, that it is ſaid to contain 18,000 or 20,000 perſons, and among theſe a conſiderable number of Spaniards; 30 miles N. of Quito. N. lat. 0° 15′. W. long. 77 56′.

OTACOUSTIC, formed from ὡς ὠτος, *ear*, and ακουω, *I hear*, a term applied to inſtruments which aid or improve the ſenſe of hearing. See Acoustic.

OTAHA, in *Geography*, one of the Society iſlands, in the South Pacific ocean, ſituated two miles N. of Ulietea, and both incloſed within one reef of coral rocks, ſo that there is no paſſage for ſhipping between them. Otaha affords two very good harbours, one on the eaſt ſide, called "Ohamene," and the other on the W., called "Ohererua," which is pretty large, and affords good anchorage in 20 and 25 fathom, nor is there any want of freſh water. The land of Otaha, as well as that of Ulietea, is hilly, broken, and irregular, except on the ſea-noaſt; yet the hills appear green and pleaſant, and are in many places clothed with wood. This iſland was conquered by the king of Bolabola. S. lat. 16° 33′. W. long. 151° 20′.

OTAHEITE, called by Capt. Wallis *King George the Third's Iſland*, an iſland in the South Pacific ocean, about 30 leagues in circumference, ſuppoſed to have been firſt ſeen by Quiros, in the year 1606, and called by him "Sagittario." Capt. Wallis was the firſt Engliſhman who diſcovered it, in 1767, and he alſo examined and deſcribed it. For his account of it ſee Hawkeſworth's Voyages, vol. i. In 1768 it was viſited by Monſ. Bougainville, and again by Capt. Cook, in the years 1769, 1773, and 1774. From his account

count of it, as drawn up by Dr. Hawkeſworth, we ſhall extract the following particulars. Our celebrated navigator came to an anchor on the 13th of April, 1769, in Port-royal bay, called by the natives "Matavai." He and his companions were hoſpitably received by the natives, who brought them in their canoes cocoa-nuts, fruit reſembling apples, bread-fruit, and ſome ſmall fiſhes, in exchange for beads and other trifles. On the 24th, Mr. (ſir Joſeph) Banks and Dr. Solander examined the country for ſeveral miles along the ſhore to the eaſtward, which for about two miles was flat and fertile; and afterwards the hills ſtretched quite towards the water's edge, and a little farther ran out to the ſea, ſo that they were obliged to climb over them. Theſe hills, which were barren, continued for about three miles more, and then terminated in a large plain, which was full of good houſes, and of people who appeared to live in great affluence. Here was a river, much more conſiderable than that at the fort of the navigators, which iſſued from a deep and beautiful valley, and at ſome diſtance from the ſea it was 100 yards wide. About a mile beyond this river, the country became again barren, the rocks every where projecting into the ſea, ſo that they reſolved to return from this excurſion. Soon after the queen of the iſland, named "Oberea," was introduced to them. She ſeemed to be about 40 years of age, was tall, and of a large make; her ſkin was white, and her eyes were animated by an uncommon degree of intelligence and ſenſibility: ſhe appeared to have been handſome when young, but few memorials of her beauty now remained. On the 26th of June, Cook and Mr. Banks ſet out in the pinnace to make a circuit of the iſland, in order to ſketch out the coaſt and harbours. Taking their route to the eaſtward, they went on ſhore in a diſtrict called "Oahounue," governed by a young chief called Ahio. They then proceeded to the harbour, in which M. Bougainville lay, called "Ohidea." This harbour lay on the W. ſide of a great bay, under ſhelter of a ſmall iſland, called "Boourou," near which is another, called "Taawirrii" In their farther progreſs, they reached a low neck of land, or iſthmus, at the bottom of the bay, that divides the iſland into two peninſulas, each of which is a diſtrict or government wholly independent of the other. From Port-royal the coaſt trends E. by S. and E.S.E. 10 miles, then S. by E. and S. 11 miles to the iſthmus. In the firſt direction the ſhore is in general open to the ſea; but in the laſt it is covered by reefs of rocks, which form ſeveral good harbours with ſafe anchorage, and other conveniences. The adjacent country was a marſhy flat about two miles over, acroſs which the natives haul their canoes to the correſponding bay on the other ſide. They then prepared to continue their route for what their guide, "Tituboalo," called the other kingdom; he ſaid that the name of it was "Tiarrabou," or "Otaheite Ete," and that of the chief who governed it "Waheatua:" they alſo learnt that the name of the peninſula, where they had taken their ſtation, was "Opoureonu," or "Otaheite Nuz." After rowing a few miles, they landed in a diſtrict which was the dominion of a chief called "Maraitata," the burying-place of men. They then proceeded to the diſtrict which was immediately under the government of the principal chief, or king of the peninſula, "Waheatua." This diſtrict conſiſts of a large and fertile plain, watered by a river ſo wide, that they were obliged to ferry over it in a canoe. In this place no houſe appeared to be inhabited, but the ruins of many that had been very large were perceived. Proceeding along the ſhore, which forms a bay, called "Oaitipeha," they found the Chief ſitting near ſome pretty canoe awnings, under which it was ſuppoſed he and his attendants ſlept. Hence they paſſed through a country that appeared to be more cultivated than any that had been ſeen in any other part of the iſland. The houſes were neither large nor numerous, but the canoes, which were innumerable, were ſuperior, both in ſize and ſtructure, to any that had been ſeen before. At almoſt every point there was a ſepulchral building, and there were many of them alſo inland. But though this part of the country was fertile and cultivated, no bread-fruit was found; the trees were bare, and the inhabitants ſeemed to ſubſiſt upon nuts, reſembling cheſnuts, and which they called "Ahee." As they proceeded they came abreaſt of a ſmall iſland called "Otooarette:" they next advanced round the S.E. point, part of which is not covered by any reef, but lies open to the ſea; and here the ſwell riſes directly from the ſhore. At the ſouthernmoſt part of the iſland the ſhore is again covered by a reef, which forms a good harbour, and the land about it is very fertile. In a long houſe at the S.E. end of the iſland, they ſaw what was altogether new to them: at one end of it, faſtened to a ſemicircular board, hung 15 human jaw-bones, which appeared to be freſh, and there was not one of them that wanted a ſingle tooth. Much as they were ſurpriſed, and anxious as they were in their inquiries concerning this circumſtance, they could obtain no information. Quitting this ſituation, they were piloted over the ſhoals by the chief "Mathiabo," who wiſhed to accompany them; and opened the bay on the N.W. ſide of the iſland, which anſwered to that on the S.E., ſo as at the iſthmus, or carrying place, almoſt to interſect the iſland, and when they had coaſted about two-thirds of it, they determined to go on ſhore for the night. Here they were hoſpitably received in the houſe of the chief of the diſtrict, whoſe name was "Wiverou." This place is ſituated on the N. ſide of "Tiarrabou," the S.E. peninſula, or diviſion of the iſland, and at the diſtance of about five miles S.E. from the iſthmus, having a large and commodious harbour, inferior to none in the iſland, about which the land is very rich in produce. Without much communication with this diviſion, they were every where received by the inhabitants in a very friendly manner: the whole diſtrict was fertile and populous, and apparently in a more flouriſhing ſtate than "Opourenou," though not above one-fourth part as large. The next diſtrict in which they landed was the laſt in "Tiarrabou," and governed by a chief, whoſe name was "Omoe." Leaving Omoe, they proceeded on their return, and ſoon reached Oppureonu, the N.W. peninſula. Here they ſaw a repoſitory for the dead, uncommonly decorated; the pavement was very neat, and upon it was raiſed a pyramid, about five feet high, entirely covered with the fruits of two plants, peculiar to this country. Near the pyramid was a ſmall image of ſtone, of very rude workmanſhip, and the firſt inſtance of carving in ſtone that had been ſeen among theſe people. It was covered by a ſhed, and ſeemed to be highly valued. They then paſſed through the only harbour on the S. ſide of Opoureonu, that is fit for ſhipping. It is ſituated about five miles to the weſtward of the iſthmus, between two ſmall iſlands that lie near the ſhore, and about a mile diſtant from each other, and affords good anchorage. Here they were not far from the diſtrict called "Paparra," which belonged to their friends Oamo and Oberea, where they propoſed to ſleep. Taking up their quarters at the houſe of Oberea, though ſhe was abſent, they determined to lodge there: the houſe was neat, though ſmall, and had at this time no inhabitant but her father, who received them kindly. Here they ſurveyed the "Morai" of Oamo and Oberea, which is an enormous pile, and the principal piece of Indian architecture in the iſland. (See MORAI.) Having paſſed the night, in perfect ſecurity and quiet, they

arrived

arrived before the next evening at "Atahourou," the reſidence of their friend "Tootahah," where they were well entertained. The next day, Saturday, July the 1ſt, they got back to their fort at Matavai, having found the circuit of the iſland, including both peninſulas, to be about 30 leagues. On the 3d of this month Mr. Banks, with ſome Indian guides, ſet out to trace the river up the valley from which it iſſues. For about ſix miles they met with houſes, not far from one another, on each ſide of the river, and the valley was every where about 400 yards wide. Having been refreſhed at the laſt houſe they met with, and having walked about ſix miles further, they paſſed under vaults formed by fragments of the rock, and ſoon after found the river banked by ſteep rocks, from which a caſcade, falling with great violence, formed a pool ſo deep, that the Indians ſaid they could not paſs it. The ſtones, which Mr. Banks examined, exhibited, like thoſe of Madeira, manifeſt tokens of having been burnt: traces of fire are alſo manifeſt in the very clay upon the hills; ſo that it may be preſumed, that this and the neighbouring iſlands, are either ſhattered remains of a continent, which ſome have ſuppoſed to be acceſſary to this part of the globe, to preſerve an equilibrium of its parts, which were left behind when the reſt ſunk by the mining of a ſubterraneous fire, ſo as to give a paſſage to the ſea near it; or were torn from rocks, which, from the creation of the world, had been the bed of the ſea, and thrown up in heaps, to a height which the waters never reach.

Among the natives who almoſt were conſtantly with our navigators, was "Tupia," who had been the firſt miniſter of Oberea, when ſhe was in the height of her power; he was alſo the chief "Takowa" or prieſt of the iſland, and conſequently well acquainted with the religion of the country, both as to its ceremonies and its principles. He had alſo great experience and knowledge in navigation, and was particularly acquainted with the number and ſituation of the neighbouring iſlands. He was therefore an inſtructive and uſeful companion; and expreſſed a deſire to accompany our navigators, with which they cheerfully complied. The beſt articles for traffic in this iſland were axes, hatchets, ſpikes, large nails, looking glaſſes, knives, and beads, for ſome of which every thing which the natives poſſeſs may be procured. They are indeed fond of fine linen cloth, both white and printed: but an ax worth half a crown will fetch more than a piece of cloth worth 20*s*.

Otaheite is ſurrounded by a reef of coral rocks, which forms ſeveral excellent bays and harbours, where there is room and depth of water for any number of the largeſt ſhips. Port-royal, or Matavai, which is not inferior to any, may be eaſily known by a very high mountain in the middle of the iſland, which bears due S. from Point Venus. The beſt anchoring is on the E. ſide of the bay, with 16 and 14 fathom upon an oozy bottom. The ſhore of the bay is a fine ſandy beach, behind which runs a river of freſh water, ſo that any number of ſhips may be ſupplied without incommoding each other.

The face of the country, except that part of it which borders upon the ſea, is very uneven; it riſes in ridges that run up into the middle of the iſland, and there form mountains, which may be ſeen at the diſtance of ſixty miles: between the foot of theſe ridges and the ſea is a border of low land, ſurrounding the whole iſland, except in a few places where the ridges riſe directly from the ſea: the border of low land is in different parts of different breadths, but no where more than a mile and a half. The ſoil, except on the very tops of the ridges, is extremely rich and fertile, watered by a great number of rivulets of excellent water, and covered with fruit-trees of various kinds. The low land that lies between the foot of the ridges and the ſea, and ſome of the vallies, are the only parts of the iſland that are inhabited, and here it is populous: the houſes do not form villages or towns, but are ranged along the whole border, at the diſtance of about fifty yards from each other, with little plantations of plantains, the tree which furniſhes them with cloth. The whole iſland, according to the beſt information, could furniſh 6780 fighting men, from which the number of inhabitants may eaſily be computed. The produce of this iſland is bread-fruit, cocoa-nuts, bananas of thirteen ſorts, plantains, a fruit not unlike an apple, which, when ripe, is very pleaſant; ſweet potatoes, yams, cocoas, a kind of arum; a fruit known here by the name of jambu, and reckoned moſt delicious; ſugar-cane, which the inhabitants eat raw; a root of the ſaloop kind, which the inhabitants call pea; a plant called ethee, of which the root only is eaten; a fruit that grows in a pod, like that of a large kidney bean, which, when it is roaſted, eats very much like a cheſnut, by the natives called ahee; a tree called wharra, called in the Eaſt Indies pandanes, which produces fruit ſomething like the pine apple; a ſhrub called nono; the morinda, which alſo produces fruit; a ſpecies of fern, of which the root is eaten, and ſometimes the leaves: and a plant called theve, of which the root alſo is eaten: but the fruits of the nono, the fern, and the theve, are eaten only by the inferior people, and in times of ſcarcity. All theſe, which ſerve the inhabitants for food, the earth produces ſpontaneouſly, or with little culture. They have no European fruit, garden-ſtuff, pulſe, or legumes, nor grain of any kind. Of tame animals, they have only hogs, dogs, and poultry; neither is there a wild animal in the iſland, except ducks, pigeons, parroquets, with a few other birds, and rats, there being no other quadruped, nor any ſerpent. But the ſea ſupplies them with great variety of moſt excellent fiſh, to eat which is their chief luxury, and to catch it their principal labour. As to the people, they are of the largeſt ſize of Europeans. The men are tall, ſtrong, well-limbed, and finely ſhaped. The women of the ſuperior rank are alſo, in general, above our middle ſtature, but thoſe of the inferior claſs are rather below it, and ſome of them are very ſmall. This defect in ſize probably proceeds from their early commerce with men, the only thing in which they differ from their ſuperiors, that could poſſibly affect their growth. Their natural complexion is that kind of clear olive or brunette, which many people in Europe prefer to the fineſt white and red. The ſkin is delicately ſmooth and ſoft; they have no tint in their cheeks, which we diſtinguiſh by the name of colour. The ſhape of the face is comely, the cheek bones are not high, neither are the eyes hollow, nor the brows prominent; the only feature that does not correſpond with our ideas of beauty is the noſe, which, in general, is ſomewhat flat: but their eyes, eſpecially thoſe of the women, are full of expreſſion, ſometimes ſparkling with fire, and ſometimes melting with ſoftneſs; their teeth are, almoſt without exception, moſt beautifully even and white, and their breath perfectly without taint. The hair is almoſt univerſally black, and rather coarſe. The men have beards, which they wear in many faſhions, always, however, plucking out great part of them, and keeping the reſt perfectly clean and neat. In their motions there is at once vigour and eaſe; their walk is graceful, their deportment liberal, and their behaviour to ſtrangers and to each other affable and courteous. In their diſpoſitions, alſo, they ſeemed to be brave, open, and candid, without either ſuſpicion or treachery, cruelty or revenge. They were, however, all thieves; and when that is allowed, they need not much fear a competition with the people of any other nation upon earth. The women

always cut their hair ſhort round their ears, and the men, except the fiſhers, who are almoſt continually in the water, ſuffer it to flow in large waves over their ſhoulders, or tie it up in a bunch on the top of their heads. They have a cuſtom alſo of anointing their heads, with what they call "monoe," an oil expreſſed from the cocoa-nut, in which ſome ſweet herbs or flowers have been infuſed: as the oil is generally rancid, the ſmell is at firſt very diſagreeable to an European, and as they live in a hot country, and have no ſuch thing as a comb, they are not able to keep their heads free from lice, which the children and common people ſometimes pick out and eat; a hateful cuſtom, wholly different from their manners in every other particular, for they are delicate and cleanly almoſt without example; and thoſe to whom captain Cook diſtributed combs, ſoon delivered themſelves from vermin, with a diligence which ſhewed that they were not more odious to us than to them. They have a cuſtom of ſtaining their bodies, nearly in the ſame manner as is practiſed in many other parts of the world, which they call "tattooing." They prick the ſkin, ſo as juſt not to fetch blood, with a ſmall inſtrument, ſomething in the form of a hoe; that part which anſwers to the blade is made of a bone or ſhell, ſcraped very thin, and is from a quarter of an inch to an inch and an half wide; the edge is cut into ſharp teeth or points, from the number of three to twenty, according to its ſize: when this is to be uſed, they dip the teeth into a mixture of a kind of lamp-black, formed of the ſmoke that riſes from an oily nut, which they burn inſtead of candles, and water: the teeth, thus prepared, are placed upon the ſkin, and the handle to which they are faſtened being ſtruck, by quick ſmart blows, with a ſtick fitted to the purpoſe, they pierce it, and at the ſame time carry into the puncture the black compoſition, which leaves an indelible ſtain The operation is painful, and it is ſome days before the wounds are healed. It is performed upon the youth of both ſexes, when they are about twelve or fourteen years of age, on ſeveral parts of the body, and in various figures, according to the fancy of the parent, or perhaps the rank of the party. The women are generally marked with this ſtain, in the form of a Z, on every joint of their fingers and toes, and frequently round the outſide of their feet: the men are alſo marked with the ſame figure, and both men and women have ſquares, circles, and creſcents, and ill-deſigned repreſentations of men, birds, or dogs, and various other devices, impreſſed upon their legs and arms, ſome of which, we were told, had ſignifications, though we never could learn what they were. But the part on which theſe ornaments are laviſhed with the greateſt profuſion, is the breech: this, in both ſexes, is covered with a deep black; above which arches are drawn one over another as high as the ſhort ribs. Theſe arches are their pride, and are ſhewn both by men and women with a mixture of oſtentation and pleaſure. The face in general is left unmarked. Some old men had the greateſt part of their bodies covered with large patches of black deeply indented at the edges, like a rude imitation of flame; but our navigators were told, that they came from a low iſland called "Nooouoora," and were not natives of Otaheite. Their clothing conſiſts of cloth or matting of different kinds. The cloth, which will not bear wetting, they wear in dry weather, and the matting when it rains; they are put on in many different ways, juſt as their fancy leads them; for in their garments nothing is cut into ſhapes, nor any two pieces ſewed together. The dreſs of the better ſort of women conſiſts of three or four pieces: one piece, about two yards wide, and eleven yards long, they wrap ſeveral times round their waiſt, ſo as to hang down like a petticoat, as low as the middle of the leg, and this they call "parou:" two or three other pieces, about two yards and a half long, and one wide, each having a hole cut in the middle, they place one upon another, and then putting the head through the holes, they bring the long ends down before and behind; the others remain open at the ſides, and give liberty to the arms: this, which they call the "tebuta," is gathered round the waiſt, and confined with a girdle or ſaſh, of thinner cloth, which is long enough to go many times round them, and exactly reſembles the garment worn by the inhabitants of Peru and Chili, which the Spaniards call "poncho." The dreſs of the men is the ſame, except that inſtead of ſuffering the cloth that is wound about the hips to hang down like a petticoat, they bring it between their legs, ſo as to have ſome reſemblance to breeches, and it is then called "maro." Upon their legs and feet they wear no covering, but they ſhade their faces from the ſun with little bonnets, either of matting or of cocoa-nut leaves, which they make occaſionally in a few minutes. This, however, is not all their head-dreſs; the women ſometimes wear little turbans, and ſometimes a dreſs which they value much more, and which, indeed, is much more becoming, called "tomou:" which conſiſts of human hair, plaited in threads, ſcarcely thicker than ſowing ſilk. Sir Joſeph Banks has pieces of it above a mile in length, without a knot. Their perſonal ornaments, beſides flowers, are few; both ſexes wear ear-rings, but they are placed only on one ſide: when our navigators came, they conſiſted of ſmall pieces of ſhell, ſtones, berries, red peas, or ſome ſmall pearls, three in a ſtring; but the beads brought by captain Cook very ſoon ſupplanted them all. The children go quite naked; the girls till they are three or four years old, and the boys till they are ſix or ſeven. The houſes, or rather dwellings of theſe people, are all built in the woods, between the ſea and the mountains, and no more ground is cleared for each houſe, than juſt ſufficient to prevent the dropping of the branches from rotting the thatch with which they are covered; from the houſe, therefore, the inhabitants ſtep immediately under the ſhade, which is the moſt delightful that can be imagined. It conſiſts of groves of bread-fruit and cocoa-nuts, without underwood, which are interſected, in all directions, by the paths that lead from one houſe to the other. The ground on which the houſe is built is an oblong ſquare, twenty-four feet long, and eleven wide; over this a roof is raiſed, upon three rows of pillars or poſts, parallel to each other, one on each ſide, and the other in the middle. The utmoſt height within is about nine feet, and the eaves on each ſide reach to within about three feet and a half of the ground: below this, and through the whole height at each end, it is open, no part of it being incloſed with a wall. The roof is thatched with palm-leaves, and the floor is covered, ſome inches deep, with ſoft hay; over this are laid mats, ſo that the whole is one cuſhion, upon which they ſit in the day, and ſleep in the night. In ſome houſes, however, there is one ſtool, which is wholly appropriated to the maſter of the family; beſides this, they have no furniture, except a few little blocks of wood, the upper ſide of which is hollowed into a curve, and which ſerve them for pillows. The houſe is, indeed, principally uſed as a dormitory; for, except it rains, they eat in the open air, under the ſhade of the next tree. The clothes that they wear in the day ſerve them for covering in the night; the floor is the common bed of the whole houſehold, and is not divided by any partition. The maſter of the houſe and his wife ſleep in the middle, next to them the married people, next to them the unmarried women, and next to them, at a little diſtance, the unmarried men; the

ſervants,

ſervants, or "toutous," as they are called, ſleep in the open air, except it rains, and in that caſe they come juſt within the ſhed. There are, however, houſes of another kind, belonging to the chiefs, in which there is ſome degree of privacy. Theſe are much ſmaller, and ſo conſtructed, as to be carried about from place to place, and ſet up occaſionally, like a tent; they are incloſed on the ſides with cocoa-nut leaves, but not ſo cloſe as to exclude the air, and the chief and his wife ſleep in them alone. There are houſes alſo of a much larger ſize, not built either for the accommodation of a ſingle chief, or a ſingle family; but as common receptacles for all the people of a diſtrict. Some of them are 200 feet long, thirty broad, and, under the ridge, twenty feet high; theſe are built and maintained at the common expence of the diſtrict, for the accommodation of which they are intended. Of the food eaten here the greater part is vegetable. Of the only animals, hogs, dogs and poultry, there are by no means plenty. When a chief kills a hog, it is almoſt equally divided among his dependants; and as they are very numerous, the ſhare of each individual at theſe feaſts, which are not frequent, muſt neceſſarily be ſmall. Dogs and fowl fall ſomewhat more frequently to the ſhare of the common people. Captain Cook could not much commend the flavour of their fowls, but thought a South Sea dog was little inferior to an Engliſh lamb; their excellence is probably owing to their being kept up, and fed wholly upon vegetables. The ſea affords them a great variety of fiſh. The ſmaller fiſh, when they catch any, are generally eaten raw, as we eat oyſters; and nothing that the ſea produces comes amiſs to them: they are fond of lobſters, crabs, and other ſhell-fiſh, which are found upon the coaſt; and they will eat not only ſea inſects, but what the ſeamen call blubbers, though ſome of them are ſo tough, that they are obliged to ſuffer them to become putrid before they can be chewed. Of their vegetables, the principal is the bread-fruit, to procure which coſts them no trouble or labour but climbing a tree: the tree which produces it does not, indeed, ſhoot up ſpontaneouſly; but if a man plant ten of them in his life-time, which he may do in about an hour, he will as completely fulfil his duty to his own and future generations, as the native of our leſs temperate climate can do by ploughing in the cold of winter, and reaping in the ſummer's heat, as often as theſe ſeaſons return; even if, after he has procured bread for his preſent houſehold, he ſhould convert a ſurplus into money, and lay it up for his children. It is true, indeed, that the bread-fruit is not always in ſeaſon; but cocoa-nuts, bananas, plantains, and a great variety of other fruits, ſupply the deficiency. Salt water is the univerſal ſauce, no meal being eaten without it: thoſe who live near the ſea have it fetched as it is wanted; thoſe who live at ſome diſtance keep it in large bamboos, which are ſet up in their houſes for uſe. For drink they have in general nothing but water, or the juice of the cocoa-nut; the art of producing liquors that intoxicate, by fermentation, being happily unknown to them: neither have they any narcotic which they chew, as the natives of ſome other countries do opium, beetle-root, and tobacco. The quantity of food which theſe people eat at a meal is prodigious; one man will devour two or three fiſhes as big as a perch, three bread-fruits, each bigger than two fiſts, fourteen or fifteen plantains or bananas, each of them ſix or ſeven inches long, and four or five round, and near a quart of the pounded bread-fruit, which is as ſubſtantial as the thickeſt unbaked cuſtard. The women not only abſtain from eating with the men, and of the ſame victuals, but even have their victuals ſeparately prepared by boys kept for that purpoſe, who depoſit it in a ſeparate ſhed, and attend them with it at their meals. After meals, and in the heat of the day, the middle-aged people of the better ſort generally ſleep: they are, indeed, extremely indolent, ſo that ſleeping and eating are almoſt their whole employment. Thoſe that are older are leſs drowſy; and the boys and girls are kept awake by the natural ſprightlineſs and activity of their age. Their amuſements are muſic, dancing, wreſtling, and ſhooting with the bow: they alſo ſometimes vie with each other in throwing a lance. Their only muſical inſtruments are flutes and drums; the flutes are made of a hollow bamboo, about a foot long, and have only two ſtops, and conſequently but four notes. The drum is made of a hollow block of wood, of a cylindrical form, ſolid at one end, and covered at the other with ſhark's ſkin: theſe they beat not with ſticks, but their hands; and they know how to tune two drums of different notes into concord. They have alſo an expedient to bring the flutes that play together into uniſon, which is to roll up a leaf ſo as to ſlip over the end of the ſhorteſt, like our ſliding tubes for teleſcopes, which they move up and down till the purpoſe is anſwered, of which they ſeem to judge by their ear with great nicety. To theſe inſtruments they ſing; their ſongs are often extempore; they call every two verſes or couplet a ſong, "palay:" they are generally, though not always, in rhime; and when pronounced by the natives, they might be diſcovered to be metre. Their candles are made of the kernels of a kind of oily nut, which they ſtick one over another upon a ſkewer that is thraſt through the middle of them; the upper one being lighted burns down to the ſecond, and ſo on to the third, &c. Among other diverſions, there is a dance, called "timorodee," which is performed by young girls, whenever eight or ten of them can be collected together, conſiſting of motions and geſtures beyond imagination wanton, in the practice of which they are brought up from their earlieſt childhood, accompanied by words, which, if it were poſſible, would more explicitly convey the ſame ideas. In theſe dances they keep time with an exactneſs which is ſcarcely excelled by the beſt performers upon the ſtages of Europe. But the practice which is allowed to the virgin, is prohibited to the married woman. The Otaheiteans are remarkable for cleanlineſs. Accordingly they waſh their whole bodies in running water three times every day. They alſo waſh not only their mouth, but their hands at their meals, almoſt between every morſel; and their clothes, as well as their perſons, are kept without ſpot or ſtain. Their principal manufacture is their cloth, which is of three kinds; and it is made of the bark of three different trees: the Chineſe paper-mulberry, the bread-fruit tree, and the tree which reſembles the wild fig-tree of the Weſt Indies. The colours with which they dye this cloth are principally red and yellow. The red is exceedingly beautiful, and of a brighter and more delicate colour than any we have in Europe. The red colour is produced by the mixture of the juices of two vegetables; neither of which ſeparately has the leaſt tendency to that hue, and is a ſpecies of fig called here "Matte," and the other the "Cordia Sebaſtina" or "Etou." Of the fig-tree the fruit is uſed, and of the "Cordia" the leaves. The yellow is made of the bark of the root of the "Morinda citrifolia," called "Nono," by ſcraping and infuſing it in water. The inhabitants of this iſland have alſo a method of dyeing yellow with the fruit of the "tamanu:" they have alſo a preparation with which they dye brown and black. Another conſiderable manufacture is matting of various kinds; ſome of which is finer and better in every reſpect than any we have in Europe: the coarſer ſort ſerves them to ſleep upon, and the finer to wear in wet weather. They are alſo very dextrous in making baſket and wicker-work; their baſkets are of a thouſand different patterns, many of them exceedingly.

exceedingly neat; and the making of them is an art that every one practiſes, both men and women. The women make little bonnets of the cocoa-nut leaf, to ſhade their faces, at ſo ſmall an expence of time and trouble, that when the ſun is again low in the evening, they throw them away. Theſe bonnets, however, do not cover the head, but conſiſt only of a band that goes round it, and a ſhade that projects from the forehead. Of the bark of a tree, called "poerou," the "Hibiſcus tiliacus" of Linnæus, they make ropes and lines, from the thickneſs of an inch to the ſize of a ſmall packthread: with theſe they make nets for fiſhing: of the fibres of the cocoa-nut they make thread, for faſtening together the ſeveral parts of their canoes, and belts, either round or flat, twiſted or plaited; and of the bark of the "erowa," a kind of nettle, which grows in the mountains, and is, therefore, rather ſcarce, they make the beſt fiſhing-lines in the world: with theſe they hold the ſtrongeſt and moſt active fiſh, ſuch as bonetas and albicores, which would ſnap our ſtrongeſt ſilk lines in a minute, though they are twice as thick. They make alſo a kind of ſeine, of a coarſe broad graſs, the blades of which are like flags; theſe they twiſt and tie together in a looſe manner, till the net, which is about as wide as a large ſack, is from ſixty to eighty fathom long: this they haul in ſhoal ſmooth water, and its own weight keeps it ſo cloſe to the ground that ſcarcely a ſingle fiſh can eſcape. In every expedient, indeed, for taking fiſh, they are exceedingly ingenious; they make harpoons of cane, and point them with hard wood, which in their hands ſtrike fiſh more effectually than thoſe which are headed with iron can do in our's, ſetting aſide the advantage of our's being faſtened to a line, ſo that the fiſh is ſecured if the hook takes place, though it does not mortally wound him. Of fiſh hooks they have two kinds, admirably adapted in their conſtruction as well to the purpoſe for which they are deſigned, as to the materials of which they are made. Theſe are made of mother-of-pearl, or ſome other hard ſhell. They have an adze of ſtone; a chiſſel, or gouge, of bone, generally that of a man's arm between the wriſt and elbow; a raſp of coral; and the ſkin of a ſting-ray, with coral ſand, as a file or poliſher. This is a complete catalogue of their tools, and with theſe they build houſes, conſtruct canoes, hew ſtone, and fell, cleave, carve, and poliſh timber. The canoes, or boats, which are uſed by the inhabitants of this and the neighbouring iſlands, may be divided into two general claſſes; one of which they call ivahahs, the other pahies. (See Boat.) In connection with their navigation we may mention their wonderful ſagacity in foretelling the weather, at leaſt the quarter from which the wind ſhall blow at any future time. In their longer voyages, they ſteer by the ſun in the day, and in the night by the ſtars; all which they diſtinguiſh ſeparately by names, and know in what part of the heavens they will appear in any of the months during which they are viſible in their horizon; they alſo know the time of their annual appearing and diſappearing with more preciſion than will eaſily be believed by an European aſtronomer. In ſpeaking of time, either paſt or future, they never uſed any term but "Malama," which ſignifies moon; of theſe moons they count 13, and then begin again, ſo that they have a notion of the ſolar year: each month, they ſay, has 29 days, including one in which the moon is not viſible. They diſtinguiſh them by ſeparate names. Every day is ſubdivided into twelve parts, each of two hours, of which ſix belong to the day and ſix to the night. In numeration they proceed from 1 to 10, the number of fingers on both hands; and though they have for each number a different name, they generally take hold of their fingers one by one, ſhifting from one hand to the other till they come to the number they want to expreſs. In counting from 10, they repeat the name of that number, and add the word *more*; ten and one more, is eleven, &c. When they come to 10 and 10 more, they have a new denomination, as we ſay a ſcore; and by theſe ſcores they count till they get ten of them, when they have a denomination for two hundred; but they did not ſeem to have any denomination for expreſſing a greater number. In ſpeaking of diſtance from place to place, they expreſs it, like the Aſiatics, by the time that is required to paſs it. Their language is ſoft and melodious; it abounds with vowels, and captain Cook's company eaſily learnt to pronounce it: but found it exceedingly difficult to teach them to pronounce a ſingle word of Engliſh; probably not only from its abounding in conſonants, but from ſome peculiarity in its ſtructure; for Spaniſh and Italian words, if ending in a vowel, they pronounced with great facility. Whether it is copious, our navigators were not ſufficiently acquainted with it to know; but it is certainly very imperfect, for it is almoſt totally without inflexion, both of nouns and verbs. Few of the nouns have more than one caſe, and few of the verbs more than one tenſe. They have, however, certain affixes, which, though but few in number, are very uſeful to them. At Otaheite they have few diſeaſes; the natives, however, are afflicted with the eryſipelas, and cutaneous eruptions of the ſcaly kind, very nearly approaching to a leproſy. Some few had ulcers on different parts of their bodies, of a virulent appearance. The method of cure that is chiefly practiſed by the prieſts of this iſland conſiſts chiefly of prayers and ceremonies. Their commerce with the inhabitants of Europe has already entailed upon them that dreadful curſe which avenged the inhumanities committed by the Spaniards in America, the venereal diſeaſe. There are two places in which their dead are depoſited; one a kind of ſhed where the fleſh is ſuffered to putrify; the other an incloſure, with erections of ſtone, where the bones are afterwards buried. The ſheds are called "Tapapow," and the incloſures "Morais." The Morais are alſo places of worſhip. As to their religion, they believe, beſides a ſupreme deity, that there are numerous ſubordinate deities, or "Eatuas," of both ſexes; the male are worſhipped by the men, and the female by the women; and each have morais to which the other ſex is not admitted, though they have alſo morais common to both: men perform the prieſtly office to both ſexes, and each ſex has its prieſts; for thoſe who officiate for one ſex do not officiate for the other. They alſo believe the immortality of the ſoul, at leaſt its exiſtence in a ſeparate ſtate, and that there are two ſituations of different degrees of happineſs, ſomewhat analogous to our heaven and hell: the ſuperior ſituation they call "tavirua l'erai," the other "liahoboo." They do not, however, conſider them as places of reward and puniſhment, but as receptacles for different claſſes; the firſt, for their chiefs and principal people; the other for thoſe of inferior rank; for they do not ſuppoſe that their actions here in the leaſt influence their future ſtate, or indeed that they come under the cognizance of their deities at all. The character of the prieſt, or "tahowa," is hereditary: the claſs is numerous, and conſiſts of all ranks of people; the chief, however, is generally the younger brother of a good family, and is reſpected in a degree next to their kings or emperors. Marriage, in this iſland, as appeared to us, is nothing more than an agreement between the man and woman, with which the prieſt has no concern. Where it is contracted, it appears to be pretty well kept, though ſometimes the parties ſeparate by mutual conſent, and in that caſe a divorce takes place with as little trouble as the marriage. Their morai, or place of worſhip, they approach with humility and reverence; and when the worſhipper brings his

offering to the altar, he always uncovers his body to the waiſt, and his looks and attitude are ſuch as expreſs a correſponding diſpoſition of mind. It did not appear that theſe people were guilty of idolatry; at leaſt they do not worſhip any thing that is the work of their hands, nor any viſible part of the creation. Although they cannot be ſaid to live under any regular form of government, yet a ſubordination is eſtabliſhed among them. Theſe orders correſpond to king, baron, vaſſal, and villain. Of the firſt order there are two in this iſland, one being the ſovereign of each of the peninſulas of which it conſiſts, and he is treated with great reſpect by all ranks. Thoſe of the next order are lords of one or more of the diſtricts into which each peninſula is divided, and of theſe there may be about 100 in the whole iſland. They parcel out their territories to thoſe of the next claſs, who cultivate, each his part, which he holds under the baron. Thoſe of the loweſt claſs reſemble the villains in feudal governments; they do all the laborious work, they cultivate the land under thoſe of the third claſs, they fetch wood and water, dreſs the victuals, and catch the fiſh. If a general attack happens to be made upon the iſland, every diſtrict under the command of the baron, or "Earee," is obliged to furniſh its proportion of ſoldiers for the common defence. The number furniſhed by all the diſtricts amounted to 6680. Upon ſuch occaſions the united force of the whole iſland is commanded in chief by the king, or "Earee rohie." Their weapons are ſlings, which they uſe with great dexterity, pikes headed with the ſtings of the ſting-rays, and clubs, of about ſix or ſeven feet long, made of a very hard heavy wood. Thus armed, they are ſaid to fight with great obſtinacy, and to give no quarter. Diſtributive juſtice, under ſuch a rude government, cannot be adminiſtered but very imperfectly; and indeed, conſidering the facility with which every appetite and paſſion are gratified, there can be little oppoſition of intereſt, and of courſe crimes are few. There is nothing like money, and this circumſtance excludes many crimes. Adultery, however, is ſometimes committed, as well as theft. Adultery, in the heat of reſentment, is ſometimes puniſhed with death, if the offending parties are caught in the act; but in ordinary circumſtances the female tranſgreſſor ſeldom ſuffers more than a beating. Puniſhment is enforced by no law, nor inflicted by the order of any magiſtrate. Though this, and the neighbouring iſlands lie within the tropic of Capricorn, yet the heat is not troubleſome, nor did the winds blow conſtantly from the eaſt. The tides about theſe iſlands are, perhaps, as inconſiderable as in any part of the world. A ſouth or ſouth-by-weſt moon, makes high water in the bay of Matavai, at Otaheite; but the water very ſeldom riſes perpendicularly above ten or twelve inches."

The variation of the compaſs is 4° 46′ E. On captain Cook's viſit to Otaheite in 1773, he was hoſpitably received; and before his departure, Capt. Furneaux took on board his ſhip a young man named Omai, a native of Ulietea, where he had ſome property, of which he had been diſpoſſeſſed by the people of Bolabola. Omai had a very good underſtanding, quick parts, and honeſt principles; his behaviour was ſuch as to render him acceptable to the beſt company, and his pride led him to avoid the ſociety of perſons of inferior rank. His paſſions were of the ſame kind with thoſe of other young men, but he had judgment to reſtrain the indulgence of them in an improper exceſs. During his ſtay in England he was introduced to his majeſty, for whom he entertained ſentiments of reſpect and gratitude; he was careſſed by many of the principal nobility, and did nothing to forfeit the eſteem of any one of them; but his principal patrons were the earl of Sandwich, ſir Joſeph Banks, and Dr. Solander. Although Omai lived in the midſt of amuſements during his reſidence in England, his return to his native country was always in his thoughts, and though he was not impatient to go, he expreſſed a ſatisfaction as the time of his return approached. He embarked with Capt. Cook in the Reſolution, when ſhe was fitted out for another voyage, loaded with preſents from his ſeveral friends, and full of gratitude for the kind reception he had experienced among us. On this viſit to Otaheite, it was found that though in the years 1767 and 1768, it ſwarmed with hogs and fowls, theſe animals were become ſcarce, and were procured with difficulty. The ſcarcity of hogs was attributed partly to the number which had been conſumed, and carried off by the ſhipping which had touched there of late years, and partly to the frequent wars between the two kingdoms.

Capt. Cook took pains to aſcertain whether, among the religious cuſtoms of the natives, human ſacrifices were not conſidered as neceſſary. He learnt upon the whole, that men for certain crimes were condemned to be ſacrificed to the gods, provided that they had not means by which to redeem themſelves. By Omai he was informed, that they offer human ſacrifices to the Supreme Being. From Cook's information we learn, that the women of Otaheite, and of the Society Iſles, have been calumniated by thoſe who repreſent them, without exception, as ready to grant the laſt favour to any man that will come up to their price. This, he ſays, is by no means the caſe; the favours of married women, and alſo of the unmarried of the better ſort, are obtained with as much difficulty here as in any other country; neither can the charge be underſtood indiſcriminately of the unmarried of the lower claſs, for many of theſe admit of no ſuch familiarities. There are, however, proſtitutes here as well as in other countries, and perhaps more in proportion. Upon a ſecond viſit to this iſland in May 1774, it was found that a very conſiderable number of canoes had been conſtructed in the courſe of eight months, and that hogs were ſo plentiful as to afford an ample ſupply. The number of war canoes raiſed and equipped by the whole iſland, amounts to 1720, manned by 68,000 able men, allowing 40 to each canoe, and as theſe cannot amount to above one-third part of the number of both ſexes, children included, the whole iſland cannot contain leſs than 204,000 inhabitants. If this number be not over-rated, we may infer from it the richneſs and fertility of the iſland, not 40 leagues in circuit, which enable it to ſupport ſuch a number of inhabitants.

The iſland of Otaheite made formerly but one kingdom; it is not known how long it has been divided. The kings of Tiarrabou are a branch of the family of thoſe of Opoureonu; at preſent the two are nearly related, and Capt. Cook thinks, that the former is, in ſome meaſure, dependent on the latter. Otoo, who was king in 1774, is ſtyled "Euree de hia" of the whole iſland, and our navigators were informed, that Waheatoua, the king of Tiarrabou, muſt uncover before him, in the ſame manner as the meaneſt of his ſubjects. Thoſe men who are the principal perſons about the king, and form his court, are generally, if not always, his relations. But though the eſtabliſhment be kingly, there was very little about Otoo, or his court, by which a ſtranger could diſtinguiſh the king from the ſubject. In his dreſs there is no pomp; and he ſubmits to the labour of paddling his canoe in common with others that are employed for this purpoſe. All have free acceſs to him, and converſe with him without ceremony; and it is obſerved, that the chiefs of the iſland are more loved than feared, and hence it may be concluded, that the government is mild and equitable.

It

It is a circumſtance, which we ſhall here mention, that the people of Otaheite are extremely fond of red feathers, eſteeming them no leſs valuable than jewels are regarded in Europe; and by a certain arrangement of them, they are uſed as ſymbols of the "Eatuas," or divinities, in all their religious ceremonies.

In Auguſt 1777, Capt. Cook again viſited Otaheite, and took Omai with him. But his conduct was ſo imprudent, that he ſoon forfeited the friendſhip of Otoo, and of every other perſon of note in the iſland. He aſſociated with none but vagabonds and ſtrangers, whoſe ſole views were to plunder him; and thus incurred the ill-will of the principal chiefs. The captain and his companions had not been forty-eight hours at anchor in Matavai bay, before they were viſited by all their old friends, none of whom came empty-handed; ſo that they were ſuperabundantly ſtocked with proviſions; nor were they under any apprehenſions of exhauſting the iſland, which preſented to their notice every mark of the moſt exuberant plenty. This viſit to the iſland afforded an opportunity of aſcertaining whether the offering of human ſacrifices conſtituted a part of the religious inſtitutions of this iſland. With this view, Capt. Cook attended Otoo to a morai at one of their public ſolemnities. He has particularly deſcribed the manner in which they were conducted. The unhappy victim, offered to the object of their worſhip on this occaſion, was a middle-aged man, who was one of the loweſt claſs of the people, and he had been ſelected, not on account of any particular crime, committed by him, meriting death. In general, however, ſuch guilty perſons are choſen for their ſacrifices; or elſe, common low fellows, who ſtroll about from place to place, and from iſland to iſland, without having any fixed abode, or any viſible way of getting an honeſt livelihood. This perſon appeared to have been privately knocked on the head with a ſtone. Thoſe who are devoted to ſuffer, in order to perform this bloody act of worſhip, are never appriſed of their fate, till the blow is given that terminates their exiſtence. Whenever any one of the great chiefs thinks a human ſacrifice neceſſary on any particular emergency, he pitches upon the victim. Some of his truſty ſervants are then ſent, who fall upon him ſuddenly, and put him to death with a club, or by ſtoning him. The king is next acquainted with it, whoſe preſence at the ſolemnities that follow is abſolutely neceſſary. The ſolemnity itſelf is called "Poore Eree," or chief's prayer; and the victim, who is offered up, "Taata-taboo," or conſecrated man. The morai, which is a place of worſhip, ſacrifice, and burial, where the ſacrifice was now offered, is that where the ſupreme chief of the whole iſland is always buried, and is appropriated to his family and ſome of the principal people; it differs little from the common ones, except in extent. Its principal part is a large, oblong pile of ſtones, lying looſely upon each other, about twelve or fourteen feet high, contracted towards the top, with a ſquare area on each ſide, looſely paved with pebble ſtones, under which the bones of the chiefs are buried. At a little diſtance from the end neareſt the ſea is the place where the ſacrifices are offered, which, for a conſiderable extent, is alſo looſely paved. Here is a very large ſcaffold, on which the offerings of fruits and other vegetables are laid. But the animals are depoſited on a ſmaller one, and the human ſacrifices are buried under different parts of the pavement. There are ſeveral other relics which ignorant ſuperſtition has ſcattered about this place. But one place, more particular than the reſt, is a heap of ſtones, at the end of the large ſcaffold, before which the human ſacrifice was offered; and on a kind of platform at one ſide are laid the ſkulls of all the human ſacrifices, which are taken up after they have been ſeveral months under ground. It cannot leſs than be regretted, that a practice ſo horrid, and ſuch bloody rites of worſhip ſhould prevail, as is probably the caſe, through all the widely extended iſlands of the Pacific ocean. There is reaſon alſo for believing, that there was a time when theſe deluded people were cannibals. Human ſacrifices are not the only barbarous cuſtom that is ſtill prevalent among this benevolent, humane people. For, beſides cutting out the jaw-bones of their enemies ſlain in battle, which they carry about as trophies, they, in ſome meaſure, offer their bodies as a ſacrifice to the "Eatooa." Soon after a battle in which they have been victors, they collect all the dead that have fallen into their hands, and bring them to the morai, where, with much ceremony, they dig a hole, and bury them all in it, as ſo many offerings to the gods; but their ſkulls are never after taken up.

Having ſettled Omai in the iſland of Huaheine, and having provided a comfortable habitation with ſuitable accommodations for him, our navigators took their leave of him on the 2d of November 1777; but in parting with Capt. Cook his feelings were much agitated, and he wept all the time in going aſhore. Whatever faults, ſays Capt. Cook, belonged to Omai's character, they were more than overbalanced by his great good-nature and docile diſpoſition. Otaheite lies in S. lat. 17° 30′ to 17° 48′. W. long. 149° 15′ to 150′. Matavai point lies in S. lat. 17° 29½′. E. long. 210° 22′ 28″. Variation of the compaſs 5° 34′ E. Dip of the needle 29° 12′. Mr. Anderſon has furniſhed ſeveral particulars of information with regard to Otaheite, which form a diſtinct chapter in the ſecond volume of Cook's third voyage. Extended as this article is, we ſhall here ſelect a few of them. There is, he ſays, ſcarcely a ſpot in the univerſe, that affords a more luxuriant proſpect than the S.E. part of Otaheite. The hills are high and ſteep, and in many places craggy. But they are covered to the very ſummits with trees and ſhrubs, ſo that the obſerver would almoſt imagine, that the rocks had the property of producing and ſupporting their verdant clothing. The flat land that bounds theſe hills towards the ſea, and the interjacent vallies, teem with various productions which grow with the moſt exuberant vigour. Nature has been no leſs liberal in diſtributing rivulets, which are found in every valley, and which, as they approach the ſea, divide into two or three branches, fertilizing the flat lands through which they run. The habitations of the natives are ſcattered without order upon theſe flats, and many of them appearing toward the ſhore, preſent a delightful ſcene to the ſhips in the harbour. It is owing to the fertility of the country, combined with the mildneſs and ſerenity of the climate, that the natives are ſo careleſs in their cultivation, ſo that in many places the ſmalleſt traces of it cannot be obſerved. The cloth plant, which is raiſed by ſeeds brought from the mountains, and the "ava," or intoxicating pepper, which they defend from the ſun when very young, by covering them with leaves of the bread-fruit tree, are almoſt the only things to which they ſeem to pay any attention; and theſe they keep very clean. Notwithſtanding the fertility of the iſland, a famine frequently happens, in which, it is ſaid, many periſh. Of animal food little falls to the ſhare of the lower claſs of people; and then it is either fiſh, ſea-eggs, or other marine productions; for they ſeldom, or ever, eat pork. It is alſo among the better ſort that the "ava" is chiefly uſed. The women not only eat by themſelves, but are excluded from a ſhare in moſt of the better ſorts of food.

One of the greateſt natural curioſities of the country is a pond or lake of freſh water, at the top of one of the higheſt mountains, remarkable for its depth, and for its eels

of an enormous ſize. The language of Otaheite, though radically the ſame with that of New Zealand and the Friendly iſlands, is deſtitute of that guttural pronunciation, and of ſome conſonants, with which theſe latter dialects abound. Like the manners of the inhabitants, the language has thus become ſoft and ſoothing. It abounds with beautiful and figurative expreſſions, which would put it upon a level, if they were known and underſtood, with many of thoſe languages that are moſt eſteemed for their warm and bold images.

In forming connections with the females, they have cuſtoms that are deemed capricious and licentious. If a young man and woman, from mutual choice, cohabit, the man gives the father of the girl ſuch things as are neceſſary in common life, as hogs, cloth, or canoes, in proportion to the time they are together; and if he thinks he has not been ſufficiently paid for his daughter, he makes no ſcruple of forcing her to leave her friend, and to cohabit with another perſon, who may be more liberal. The man is always at liberty to make a new choice, but ſhould his conſort become pregnant, he may kill the child; and after that continue his connection with the mother, or leave her. It is thought no crime in the man to join a more youthful partner to his firſt wife, and to live with both. But the cuſtom of changing their connections is more common, and is ſpoken of with great indifference. The "Erreoes" are only thoſe of the better ſort, who from being able to purchaſe a ſucceſſion of freſh connections, are conſtantly roaming about and changing. So agreeable is this licentious plan of life to their diſpoſition, that the moſt beautiful of both ſexes thus ſpend their youthful days, habituated to the practice of enormities that would diſgrace the moſt ſavage tribes; but are peculiarly ſhocking amongſt a people, whoſe general character, in other reſpects, has evident traces of the prevalence of humane and tender feelings. When an "Erreoe" woman is delivered of a child, a piece of cloth, dipped in water, is applied to the mouth and noſe, which ſuffocates it. The women are frequently treated with harſhneſs and even brutality. Nothing is more common than to ſee the men beat them without mercy. Cutting or inciding the foreſkin (not circumciſion) is a practice adopted among them from a notion of cleanlineſs; and they alſo apply reproachful appellations to thoſe who do not obſerve that cuſtom.

As to their religious ſyſtem, it is extenſive and in many inſtances ſingular; but few of the common people are acquainted with it; the knowledge of it being confined to their prieſts. They do not ſeem to pay reſpect to one god, as poſſeſſing pre-eminence, but believe in a plurality of divinities, who are all very powerful. Their aſſiduity in ſerving their gods is very conſpicuous. Their prayers are very frequent, which they chant, much after the manner of the ſongs in their feſtive entertainments. The women, as in other caſes, are obliged to ſhew their inferiority in religious obſervances; for they are required to uncover themſelves in paſſing the morai; or take a conſiderable circuit in avoiding them. They are apprehenſive of the power of ſome inauſpicious being to hurt them. They ſay, that "Etee" is an evil ſpirit, who ſometimes does them miſchief; and to whom, as well as to their god, they make offerings. But the miſchiefs they apprehend from any ſuperior inviſible beings are confined to things merely temporal. Believing the ſoul to be both immaterial and immortal, they ſay, that it flutters about the lips during the pangs of death, and that then it aſcends, and mixes with, or as they expreſs it, is eaten by the deity. In this ſtate it remains for ſome time; and then departs to a certain place, deſtined for the reception of the ſouls of men, where it exiſts in eternal night, or, as they ſometimes ſay, in twilight, or dawn. They have no idea of any permanent puniſhment after death for crimes committed upon earth; for the ſouls of good and of bad men are eaten indiſcriminately by God. But they conſider this coalition with the deity as a kind of purification, neceſſary to be undergone, before they enter a ſtate of bliſs. For, according to their doctrine, if a man refrain from all connection with women ſome months before death, he paſſes immediately into his eternal manſion, without ſuch a previous union. Some of their notions about the deity are extravagantly abſurd; conceiving that he is ſubject to be deſtroyed by ſpirits to whom he has given exiſtence, and that afterwards he has the power of re-creating himſelf. They maintain, among other ſingularities, that not only all other animals, but trees, fruit, and even ſtones, have ſouls, which at death, on being conſumed or broken, aſcend to the divinity, with whom they firſt mix, and afterwards paſs into the manſion allotted for each. They believe that ſudden death, and all other accidents, are effected by the immediate action of ſome divinity. They have confidence in dreams, which they ſuppoſe to be communications either from their god, or from the ſpirits of their departed friends, enabling thoſe favoured with them to foretell future events; but this kind of knowledge is confined to particular people. Omai pretended to have this gift. They have traditions concerning the creation, which, as we may naturally imagine, are complex, and clouded with obſcurity. They have all many legends, both religious and hiſtorical.

The boundaries of the ſeveral diſtricts, into which Otaheite is divided, are, generally, either rivulets, or low hills, which in many places jet out into the ſea. But the ſubdiviſions into particular property are marked by large ſtones, which have remained from one generation to another. The removal of any of theſe gives riſe to quarrels, which are decided by arms; each party bringing his friends into the field. But if any one complain to the "Eree de hai," he terminates the difference amicably.

The number of inhabitants in both peninſulas of Otaheite is ſtated, in the "Miſſionary Voyage," to be about 50,000; and this eſtimate, though lower than that of captain Cook, is thought greatly to exceed the population. For other particulars reſpecting the diſpoſition and character, the manners and cuſtoms, the occupations and amuſements of the Otaheiteans, as they do not materially differ from thoſe of captain Cook and his aſſociates, we refer to the appendix of the Miſſionary Voyage, 4to. Lond. 1799.

OTAKOOTAIA, or WEENOOAETTE, ſignifying little iſland, an iſland of the South Pacific ocean, about three miles in circuit; diſcovered by captain Cook in the year 1777. The beach, within the reef, is compoſed of a white coral ſand; above which, the land within does not riſe above ſix or ſeven feet, and is covered with a light reddiſh ſoil; but is entirely deſtitute of water. The only common trees found there were cocoa-palms, of which there were ſeveral cluſters, and vaſt numbers of the "wharra." A ſort of bind-weed covers the vacant ſpaces; except in ſome places, where was found a conſiderable quantity of treacle-muſtard, a ſpecies of ſpurge, with a few other ſmall plants, and the "morinda citrifolia," the fruit of which is eaten by the natives of Otaheite in times of ſcarcity. The only bird ſeen among the trees was a beautiful cuckoo, of a cheſnut-brown, variegated with black. But upon the ſhore were ſome egg-birds, a ſmall ſort of curlew, blue and white herons, and great numbers of noddies. Here was found a lizard, of a moſt forbidding aſpect, though ſmall, running up a tree; and many of another ſort were ſeen.

The banks toward the ſea were frequented by an infinite number of a ſort of moth, elegantly ſpeckled with red, black, and white. There were alſo ſeveral other ſorts of moths, as well as ſome pretty butterflies, and a few other inſects. Although no fixed inhabitants were found on this iſland, indubitable marks remained of its being, at leaſt, occaſionally frequented. Some huts were found; and alſo ſeveral large ſtones, erected, like monuments, under the ſhade of ſome trees; and ſeveral ſpaces incloſed with ſmaller ones; where, probably, the dead had been buried; and, in one place, a great many cockle-ſhells of a particular ſort, finely grooved, and larger than the fiſt were to be ſeen; from which it was reaſonable to conjecture, that the iſland had been viſited by perſons who feed, partly, upon ſhell-fiſh; about three or four leagues from Wateeoo. S. lat. 19° 15′. E. long. 201° 37′. Cook's Third Voyage, vol. i.

OTALGIA, from ους, *the ear*, and αλγος, *pain*, a pain in the ear.

OTANGURA, in *Geography*, a town of Bengal; 16 miles S.S.W. of Tomar.

OTARDIS. See BUSTARD.

OTCHAKOV, in *Geography*, a town of Ruſſia, in the government of Ekaterinoſlav, at the mouth of the Dnieper, on the Black ſea. This town has been of conſiderable importance to the Turks, as a harbour for their gallies againſt the Corſairs; and being always fortified and garriſoned, it ſerved them to act againſt the Ruſſians. The colony of Mileſians, by whom it was founded, called it "Olbis." In 1737 it was beſieged by the Ruſſians under count Munich, who carried it by aſſault on the third day after opening the trenches. In the following year the Ruſſians evacuated it, after having demoliſhed the works. In 1789 it was again beſieged by the Ruſſians under prince Potemkin, and taken by ſtorm. On this occaſion, 6000 Turks were killed and 300 made priſoners; and the Ruſſians loſt about 4000 men. It was formerly a place of conſiderable trade, but ſince the eſtabliſhment of Odeſſa, its trade has declined: 40 miles W. of Cherſon. N. lat. 46° 44′. E. long. 31° 34′.

OTCHIER BAY, a bay on the N. coaſt of South America, W. of the river Urano and E. of cape Caldero; 10 miles W. of Cumana.

OTCHI-HOTUN, a town of Aſia; 150 miles N.E. of Caſhgar. N. lat. 40° 46′. E. long. 84° 14′.

OTEAVANOOA HARBOUR, a bay on the S.W. coaſt of the iſland of Bolabola. This is one of the moſt capacious harbours captain Cook ever met with.

OTENCHYTES, from ωτος, the genitive of ους, *the ear*, and εγχευω, *to pour in*, a ſyringe for the ear.

OTHER, in *Biography*, a celebrated Norwegian, who reſided ſome time at the court of Alfred the Great. He was a man of great conſideration in his own country, though his whole riches conſiſted of no more than twenty head of cattle, twenty ſheep, and as many ſwine, and being poſſeſſed of an enterpriſing ſpirit, he undertook a voyage of diſcovery towards the White ſea; and another towards Sweden, on the ſhores of the Baltic. Alfred, who had been at Rome, where he probably collected the materials for his Geography, having cauſed the Ormeſta or Hormeſta of Oroſius to be tranſlated into the Anglo-Saxon; introduced into it the relations of Other, and of Wulfſtan, a Dane, who, perhaps, became acquainted with Other in the courſe of his travels, or reſided with him in England. Alfred's account of the voyages of Other and Wulfſtan is ſaid to be exceedingly valuable, as containing the beſt information with regard to the geography of the northern regions in the ninth century. Gen. Biog.

OTHERA, in *Botany*, a genus of Thunberg's, very nearly allied to *Orixa*. Of its etymology we are unable to form a conjecture. Thunb. Nov. Gen. 56. Japon. 4. Willd. Sp. Pl. v. 1. 671. Juſſ. 288.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Berberides*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, cloven into four ovate ſegments. *Cor.* Petals four, ovate, blunt. *Stam.* Filaments four, inſerted at the very baſe of the petals, oppoſite to them, and about half their length; anthers twin, with four furrows. *Piſt.* Germen ſuperior, ſmooth; ſtyle none; ſtigma ſeſſile. *Peric.* unknown, probably a capſule.

Eſſ. Ch. Petals four, ovate, flat. Calyx four-cleft. Stigma ſeſſile. Capſule?

1. O. *japonica*. Linn. Syſt. Veg. ed. 14. 158. Thunb. Japon. 61.—Native of Japan, where it is called *Mukade Ko*, that is *Millepeda*. *Stem* ſhrubby, with round, ſtriated, purple *branches*. *Leaves* alternate, ſtalked, ovate, obtuſe, undivided, ſmooth, coriaceous, ſpreading. *Flowers* axillary, cluſtered, white.

OTHMAN, in *Biography*, the third Saracen caliph, was one of the companions and ſecretary of Mahomet. On the death of Omar, in the year 634, the choice of a ſucceſſor was left to ſix electors, who concurred in the nomination of Othman, after he had ſolemnly promiſed to govern according to the rules of the Koran. He was far advanced in life when he came to the throne, eſteemed for his piety and integrity, and diſtinguiſhed by the ſame ſimplicity of manners which had characteriſed his two predeceſſors. His firſt public act was to ſend a body of troops to complete the reduction of Hamadan, while another body entered Perſia, whence they totally expelled the unfortunate prince Yeſdejerd. The caliph ſhewed an unjuſtifiable partiality for his own relations, by appointing his foſter-brother Abdallah-ebn-Said to ſuperſede the renowned Amru in the government of Egypt, which he had conquered. This meaſure was as diſagreeable to the Arabians as to the Egyptians, and its conſequence was a revolt of the Alexandrians, who ſurrendered their city to the Greek emperor. Othman, thus made ſenſible of his fault, reſtored the government to Amru, who recovered Alexandria, though not without loſs and difficulty. Moawiyah, about the ſame time, took the iſle of Cyprus, and the important Syrian ſea-port of Aradus. The iſle of Rhodes afterwards fell under his power. Another Moſlem army reduced all that part of Khoraſan which had not then ſubmitted to the Mahometan yoke. From Upper Egypt Abdallah-ebn-Said made an incurſion into Nubia, the Chriſtian ſovereign of which country he reduced to beg for peace, on condition of becoming his tributary. While the Moſlem empire was thus extending on all ſides under the auſpices of Othman, the caliph himſelf was in danger of loſing the affection of his ſubjects, by the weakneſs of his meaſures. Several charges were exhibited againſt him, of which one was his laviſh donations to his favourites out of the public treaſury. Othman told the aſſembled people, that money in the treaſury was a ſacred depoſit, appropriated to the ſervice of God, and that he, as the ſucceſſor of the apoſtle of God, had a right to diſpoſe of it according to his own pleaſure. An aged companion of the prophet ventured to declare his diſapprobation of what he had heard; upon which he was ſo maltreated by the partizans of Othman, that he was left for dead. This cruel and unjuſt act ſo inflamed the paſſions of the people, that they inſiſted upon Othman's abdication. He again ſaw his error, and promiſed a redreſs of grievances; but his apparent

parent condeſcenſion only increaſed their violence. At length Ali, the ſon-in-law and nephew of Mahomet, who had a conſiderable party among the inſurgents, was induced to uſe his influence for the reſtoration of tranquillity, which was effected by his joining the caliph in a promiſe to remove the cauſes of complaint. Intrigues were, however, formed to depoſe him; and by the circulation of ſome wicked calumnies, Mahomet became again his enemy, and with his party inveſted the caliph's palace, denouncing vengeance againſt his perſon. Othman requeſted aid from Ali, who ſent his ſons, Haſſan and Hoſein, to defend the gates of the palace. This they faithfully performed for ſeveral days, till at length, either for want of water, or of a hearty inclination, they withdrew, and left the caliph to the mercy of his enemies. But mercy had fled from their hearts, and Othman, placing the Koran in his boſom, waited to receive his aſſaſſins. Mahomet ſeized him by the beard, and plunged his ſword into his breaſt. Others pierced his body in different parts, and he expired under multiplied wounds. For three days his corpſe lay unburied, and expoſed to the inſults of the multitude; and at length it was without ceremony thrown into a hole. This happened in the year 655, and in the twelfth year of the caliph's reign. He was a man of a majeſtic figure, and venerable aſpect, pure in his morals, but did not poſſeſs a mind at all adapted to the duties of his ſtation. Univer. Hiſt. Gibbon.

Othman, or Osman, the founder of the Ottoman dynaſty, was the ſon of Orthogrul, a Turkman or Oguzian chieftain, who had entered into the ſervice of Aladin, ſultan of Iconium, and had eſtabliſhed himſelf with his tribe at Surgut, on the banks of the Sangar. Aladin had made him lieutenant-general; and after the death of that ſultan, great diſſenſions aroſe among his officers, who at length agreed to join their forces, and make conqueſts on the Greek empire in Leſſer Aſia. When the diviſion of the conquered countries was made, Bithynia fell to the lot of Othman. On the 27th of July 1299, having forced the ſlightly guarded paſſes of mount Olympus, he firſt invaded the territory of Nicomedia; and "the ſingular accuracy of the date," ſays the hiſtorian, "ſeems to diſcloſe ſome foreſight of the rapid and deſtructive growth of the monſter. The annals of the twenty-ſeven years of his reign would exhibit a repetition of the ſame inroads; and his hereditary troops were multiplied in each campaign, by the acceſſion of captives and volunteers. Inſtead of retreating to the hills, he maintained the moſt uſeful and defenſible poſts, fortified the towns and caſtles, which he had firſt pillaged, and renounced the paſtoral life for the baths and palaces of his infant capital." In the courſe of many years of active ſervice, he made himſelf maſter of the whole of Bithynia; and though he was repulſed in his attempts upon Nicomedia and Pruſa, he awed thoſe cities by the conſtruction of ſtrong forts in their neighbourhood. At length his ſon Orchan gained poſſeſſion of Pruſa; but the welcome news of this important conqueſt did not arrive till Othman was almoſt inſenſible to glory, by the ſevere preſſure of old age and infirmities. He died in 1326, in the 69th year of his age, and 27th of his reign, reckoning from his invaſion of Bithynia. This was the commencement of the Turkiſh empire, which, from his name, has taken the appellation of the Ottoman Porte. The glory of Othman is chiefly founded on that of his deſcendants; but the Turks have tranſcribed or compoſed a royal teſtament of his laſt counſels of juſtice and moderation. Univer. Hiſt. Gibbon, vol. xi.

OTHO, M. Salvius, in *Biography*, a Roman emperor, was deſcended from a conſular family; and in the beginning of the reign of Nero, or about the year 55, he was diſtinguiſhed as a young man of graceful perſon but licentious manners, and even well fitted as a companion to the emperor in his debaucheries. While in poſſeſſion of imperial favour he contracted an acquaintance with the beautiful Poppæa Sabina, the wife of Rufus Criſpinus, which was followed by a divorce from her huſband and a marriage with her lover. Otho, from whatever motive, was continually extolling to the emperor, in the moſt rapturous terms, the happineſs which Poppæa afforded him. Nero, inflamed by theſe repreſentations, deſired that he might have an interview with the lady, who employed her charms ſo effectually, that he was entirely captivated. He carried her off from her huſband, and when Poppæa, to ſecure his affections by jealouſy, expreſſed a great fondneſs for Otho, that Nero forbid him his palace, and would probably have gone the length of putting him to death, had not Otho's friend, Seneca, ſuggeſted his appointment to the government of Luſitania, by way of an honourable exile. In this ſituation he conducted himſelf with great credit, acquired a new character, and was diſtinguiſhed for the uprightneſs and gravity of his adminiſtration. He had reſided ten years in his province, when, on the declaration of Galba againſt the tyranny of Nero A. D. 68, he was the firſt perſon in office who joined his party, probably with a view to the ſucceſſion of the empire by means of the adoption of Galba. When this emperor was ſeated on the throne ſuch a meaſure was propoſed to him by Vinius, whoſe daughter Otho was engaged to marry, but Galba was not of the ſame opinion, he preferred the mature and rigid virtue of Piſo as the ſubject he choſe to adopt. Otho reſented this determination, and he reſolved to make himſelf maſter of the treaſures of the empire, and having ſet his mind upon obtaining the ſovereign authority, he prepared the way for his elevation by the extraordinary attention which he paid to gain the affections of the ſoldiery, in which he ſucceeded beyond any man of his time. When his plans were matured, he fixed on two common ſoldiers to ſpread diſaffection through the legions quartered in Rome, and at a proper moment Otho appeared in a public place, and was ſaluted emperor by a ſmall party of the prætorians, conſiſting only of twenty-three. He was at firſt intimidated at the ſmallneſs of the number, and would have retreated, but the ſoldiers, placing him in a chair, carried him with ſwords drawn to the camp, where the whole body joined in the ſalutation. The revolt ſpread to the other troops, and Galba advancing to the forum, was abandoned by his friends and baſely murdered. (See Galba.) Otho was immediately recognized as lawful emperor by that very ſenate which had raiſed and ſupported Galba, and he began his reign in January A. D. 69. One of his firſt acts was to admit Marius Celſus, who had been the deſignated conſul under Galba, among his confidential friends. He ſacrificed to the public hatred Tigellinus, the hated miniſter of Nero; but on the memory of that bloody emperor he ſhewed a diſpoſition to confer honours. He felt himſelf in a ſituation of great danger, and was glad to cultivate popularity with all claſſes of the people, for a ſtorm appeared which threatened to ſubvert his throne. The legions quartered in Germany, which were always the ſtrength of the Roman armies, had thrown off their allegiance to Galba, and had declared Vitellius emperor, and ſuch was their impatience to give a maſter to the Roman world, that they had ſet out on their march for Rome before they received the news of the death of Galba. They were joined by the troops in Gaul; and ſeveral places in Italy declared for Vitellius, after his lieutenant Cæcina, at the head of the firſt diviſion, had croſſed the Alps. Rome was now in the greateſt conſternation at the proſpect of the approaching civil war.

The

The two chiefs, Otho and Vitellius, reciprocally employed aſſaſſins to remove their rivals, but at the ſame time the family of Vitellius remained at Rome in ſafety, as a pledge for the ſecurity of that of Otho, ſhould fortune throw it in the power of the former. In the midſt of the alarms excited by this ſtate of affairs, a ſedition of the prætorians had nearly produced a terrible deſtruction at Rome. They ſeized upon their arms, murdered ſome of their officers, and conceiving that the ſenate was planning treaſon againſt their emperor, reſolved upon the extermination of the whole order. Otho was on that evening giving an entertainment to a numerous company of perſons of high diſtinction of both ſexes, who were ſtruck with the utmoſt terror, ſuſpecting that it might have been a plot contrived by the emperor for their deſtruction. He ſoon, however, convinced them that their fears did him injuſtice, and ſent them home by private ways, at the time that the ſoldiery were breaking into the palace. He had now to contrive means to appeaſe the inſurgents, which he did effectually by donatives well applied. Otho reſolved to meet the approaching danger, and quitting Rome at the head of his troops, he went to defend the paſſage of the Po. Every thing ſeemed to be unfavourable to the cauſe of Otho, though he himſelf is deſcribed by Tacitus, as having left all his luxurous indulgences behind him, and marching on foot, clad in ſteel, and covered with duſt. The chiefs of the ſenate were grown old and impotent; the rich men of Rome were indolent and ſlothful; the knights had long been diſſolved in eaſe and luxury, and the cohorts themſelves were relaxed from the military diſcipline of their anceſtors. Otho it is true was powerful, with regard to numbers; but his men, being little uſed to war, could not be relied upon. He ſeemed, by his behaviour, to be ſenſible of the diſproportion of the forces, and is ſaid to have been tortured with frightful dreams, and the moſt diſmal apprehenſions. With this temper he became impatient for an engagement, contrary to the opinion of his moſt prudent officers, who depended on ultimate ſucceſs chiefly from foreign armies attached to their party. They were, however, obliged to ſubmit to the emperor's determination, which was ſupported by his flatterers, by whom alſo he was perſuaded to the inglorious, and, as it proved, the prejudicial ſtep of retiring from the army with a part of the guards, before the commencement of the action. Between Cremona and Bebriacum the fatal battle was fought. The ſuperior diſcipline of the legions of Vitellius turned the ſcale of victory. Otho's army fled in the utmoſt confuſion to Bebriacum. Otho received the fatal news at Brixellum, whither he had retired, and his firſt thought was to deſtroy himſelf, as the only means of freeing himſelf from his cares, and his country from the dire calamities of a civil war. The ſoldiers flocked round him, beſeeching him to live, and to confide in their fidelity and valour for retrieving his affairs. They embraced his knees, kiſſed his hand, and gave every demonſtration of their adherence and attachment. A common ſoldier, ſeeing him immoveable, drew his ſword, and exclaiming, "From this Cæſar, judge of our fidelity, for there is not a man among us who would not do as much to ſerve you," plunged it into his own body, and fell dead at his feet. "No more ſuch brave men," cried Otho, "ſhall loſe their lives on my account." He accordingly mounted the tribunal, and made a moſt pathetic ſpeech to his ſoldiers, in which he gave reaſons for declining the conteſt. "I can never," ſaid he, "ſo much advance the intereſts of my country by war and blood, as by ſacrificing myſelf for its peace. Others have purchaſed real fame by good government, let it be my glory to leave an empire, rather than, by my ambition, to weaken or deſtroy it." He expreſſed the greateſt ſatisfaction and gratitude for the attachment he had met with, and then announced his final deciſion. He earneſtly exhorted all who adhered to him to ſubmit in time to the conqueror, that they might deſerve and obtain his clemency. He took meaſures to expedite their departure, and divided his jewels and money among his friends. Then retiring to a private chamber, he wrote conſolatory letters to his ſiſter, and to a lady whom he deſigned to marry. Hearing a tumult among the ſoldiers, he went out and quieted them, and returning to his chamber, he drank a draught of cold water, tried the points of two daggers, and placed the ſharpeſt under his pillow. He lay down in perfect tranquillity, and paſſed ſome hours in ſleep. At day-break Otho gave himſelf the mortal ſtroke, and expired in the arms of thoſe who entered on hearing his groans. The ſoldiers aſſembled at the mournful news, and with bitter lamentations carried his body to the funeral pyre. Several ſlew themſelves as a ſacrifice to his manes, and many in the neighbouring quarters, when they heard of the event, fell by mutual wounds. Otho died at the age of thirty-ſeven, after a reign of three months. There is ſomething in the concluſion of this prince's reign, that almoſt atones for the methods which he adopted to acquire dominion. The faults of his life were, in the general opinion, obliterated by the glory of his death.

Otho I., ſurnamed the *Great*, emperor of Germany, was the ſon of Henry, of the houſe of Saxony, and inherited from his father, the duchy of Saxony, Weſtphalia, Thuringia, and ſeveral other diſtricts on the Weſer and Elbe. After the death of Henry, in 936, Otho was elected emperor, and crowned at Aix-la-Chapelle in the following year. Juſt and upright in his adminiſtration, he ruled for a conſiderable time in tranquillity, till the diſturbances of thoſe unſettled times obliged him to draw the ſword. His arms were firſt directed againſt the Hungarians, who made an irruption into Franconia and Saxony, and laid waſte the country. Otho defeated them with great ſlaughter: he was next engaged in a long war with Boleſlaus, duke of Bohemia, whom he at length reduced to ſubmiſſion. After this Otho was called upon to interpoſe in a diſpute between Everhard, duke of Franconia, and Henry, duke of Brunſwick: he cauſed the former, with his principal adherents, to be tried, and condemned them to the ſingular puniſhment of each carrying a dog upon his ſhoulders from the place of his dwelling to Magdeburg. Henry, who was Otho's brother, afterwards made a league, with Everhard and the duke of Auſtriaſia, againſt the emperor, which brought on a battle, in which the latter was victorious. He was equally ſucceſsful on the other ſide of the Rhine, where he made himſelf maſter of Lorraine, and other diſtricts on the weſtern banks of the river, and laid the foundation of the palatinate of the Rhine. Lewis IV. of France married the ſiſter of Otho to ſtrengthen himſelf againſt his diſaffected ſubjects, an alliance, however, that did not prevent the emperor from entering France in 942, and expelling Lewis from Champagne. After this he took part with Lewis againſt Hugh the Great, father of Hugh Capet, and in conjunction with him took Rheims in 945. In 949, in conſequence of the maſſacre, by the Danes, of the Saxon colony ſettled in Sleſwick, Otho marched with an army into Jutland, where he had a battle with king Harold. The reſult was a treaty, by which the emperor was to keep a garriſon at Sleſwick, and Harold was to permit the Chriſtian religion to be preached in his dominions. In 955 the Hungarians entered Germany in vaſt numbers, and penetrating as far as Swabia, laid ſiege to Augſburg. Otho immediately aſſembled the force of the empire to oppoſe them, and after an obſtinate engagement defeated them with great ſlaughter. His reputation at this period procured him two diſtant embaſſies of friendſhip, one from Abderame, the

Mooriſh king of Cordova, the other from Helen, queen of the Ruſſians, who requeſted him to ſend miſſionaries in order to inſtruct her ſubjects in the doctrines of Chriſtianity. The oppreſſions of Berenger in Italy continuing, Otho ſent his ſon Ludolf to check his tyranny, who defeated him in ſeveral engagements, but was himſelf cut off by a premature death. Otho himſelf, ſolicited by the pope to come to the deliverance of the church, and promiſed the imperial crown as a recompence, in 960 marched into Italy at the head of a powerful army. Berenger did not wait for his approach; and at Milan he was crowned king of Italy. In the next ſpring he advanced to Rome, where he received the imperial crown from the hands of John XII., and from this era, according to Gibbon, "two maxims of public juriſprudence were introduced by force and ratified by time. 1. That the prince who was ſelected in the German diet, acquired from that inſtant the ſubject kingdoms of Italy and Rome: but 2. That he might not legally aſſume the titles of emperor and Auguſtus, till he had received the crown from the hands of the Roman pontiff." Otho beſtowed ſplendid gifts upon the church of St. Peter, and reſtored to the papal ſee the domains that had been wreſted from it, but at the ſame time he impoſed an oath upon the ſenate and people of Rome, that they would never elect a pope without his conſent. The pope, finding that he had procured a maſter in an ally, invited, as ſoon as Otho had withdrawn his army from Rome, Adelbert, the ſon of Berenger, and entered into a treaty with him for the expulſion of the Germans. The emperor thereupon convoked a council, which depoſed John, on the charge of his ſcandalous life, and elected a new pope under the name of Leo VIII. This pope, in gratitude for his elevation, confirmed to Otho and his ſucceſſors the prerogative granted to Charlemagne, of nominating popes and conferring inveſtiture on biſhops. On the death of John, which happened ſoon after, his adherents choſe Benedict V. in his ſtead. The emperor returning to Rome, depoſed him and replaced Leo on the throne, and then went back to Germany. On the death of Leo, John XIII. was choſen, in compliance with the recommendation of Otho, but the Romans ſoon after impriſoned him, and renounced their allegiance to the emperor. Upon this he recroſſed the Alps in 967, viſited Ravenna, and other Italian cities, and cauſed his ſon Otho to be crowned at Rome, as his partner in the empire. At Capua he received an embaſſy from the Greek emperor, Nicephoras Phocas, who propoſed a renewal of the alliance between the two empires, and requeſted his aid to expel the Saracens from Calabria. Otho gave a favourable reply to the embaſſadors, and made overtures of marriage between his ſon and Theophano, ſtep-daughter of the Greek emperor. The embaſſadors whom he ſent to Conſtantinople for the purpoſe of regulating the nuptials, were treacherouſly maſſacred, which violation of the laws of nations Otho revenged, by ſending an army to ravage the Greek poſſeſſions in Calabria. After the death of Nicephorus, an agreement was entered into with his ſucceſſor, John Zimices, and the marriage was conſummated. Not long after, in the enjoyment of peace and proſperity, this emperor died, of an apoplectic diſorder, in the year 972, after a long and active reign, during which he gave ſome extraordinary proofs of piety, courage, and generoſity, on account of which he juſtly acquired the epithet of Great. His conſort Alix retired into a convent immediately after his deceaſe; and his remains were interred, with due ſolemnity, in the cathedral church of Magdebourg, where his tomb is ſaid to be ſtill diſtinguiſhed by a Latin inſcription. Univer Hiſt. Gibbon.

Otho II., emperor of Germany, ſon of the preceding, ſucceeded his father to the imperial crown, though oppoſed by Henry, duke of Bavaria, who was proclaimed emperor at Ratiſbon, but who was ſoon obliged to renounce his title and alſo relinquiſh his duchy. Otho next found himſelf involved in a troubleſome war with Lotharius, king of France; at firſt he attempted to appeaſe the French king by ſome important conceſſions, but this proving unſucceſsful, he aſſembled an army of 60,000 men, made an irruption into the enemy's country, and committed ſuch dreadful ravages, that he quickly had peace on his own terms. In this expedition, however, he was expoſed to imminent danger by an inundation of the river Aiſne, which deſtroyed a conſiderable part of his army. After devoting ſome time to the arrangement of his affairs in Germany, he led a numerous body of forces into Italy, in order to puniſh a revolt of the Romans, and to recover Apulia and Calabria, which had been recently taken by the Greeks and Saracens. He accordingly entered Rome without oppoſition, and ſoon after hazarded a battle with the enemy, but his army was defeated, and he himſelf was reduced to the neceſſity of committing himſelf to the mercy of the waves in a ſolitary veſſel, having firſt ſtripped himſelf of his imperial robes. This ſhip was taken by corſairs, to whom he promiſed a large ſum for a ranſom, and while they were heſitating, he took the opportunity of throwing himſelf into the ſea and ſwimming aſhore at Roſani, where the empreſs then was. Soon after this event he renewed the war with vigour, and his exertions were attended with ſuch ſignal ſucceſs, that the Saracens in Italy were utterly exterminated. He then chaſtiſed the puſillanimous troops who had deſerted him in a former engagement; gave up the town of Beneventum to military execution, for having furniſhed his enemies with proviſions; and revenged himſelf for the defection of the Romans, by cauſing many of the principal citizens to be maſſacred at a banquet. This ſavage act obtained for him the title of the "Sanguinary." After this he marched into Lombardy, and held an aſſembly of the ſtates of Italy and Germany at Verona, in which he cauſed his young ſon Otho to be recognized as heir of the empire. He then returned to Rome, where he fell ill, and died in the year 983, having ſat upon the throne between ten and eleven years. His death has been differently accounted for; ſome ſay it was occaſioned by the wound of a poiſoned javelin, received in his war with the Greeks, and others aſſert that his death was haſtened by the imprudent behaviour of his empreſs Theophania, who had publicly exulted in the victories of her countrymen, though it was obtained over her huſband. His own opinion of the reliance to be placed on his Italian ſubjects, was ſhewn by a law, in which he forbade their evidence to be taken even on oath. Univer. Hiſt. Gibbon.

Otho III., emperor of Germany, ſon of the preceding, was twelve years of age when he ſucceeded to the throne, on which account he obtained the ſurname of the "Infant," but when this appellation was no longer applicable, he acquired the epithet of "Rufus." Henry, duke of Bavaria, nephew of Otho I., took poſſeſſion of the perſon of the young prince, under pretence of the right of guardianſhip, but a conſiderable number of the German princes aſſembling, delivered him from the duke's cuſtody, and cauſed him to be proclaimed emperor with the uſual ſolemnities. While the other parts of his dominions ſubmitted to his authority, the city of Rome ſhook off the German yoke in favour of Creſcentius, governor and titular conſul of that city. The commencement of this reign was diſturbed by hoſtile incurſions of the Danes and Sclavonians, but the imperial arms were at length decidedly victorious. About this time a furious conteſt began between Charles, duke of

of Lorrain, and Hugh Capet, which terminated in the captivity of the former, and the exaltation of his rival to the crown of France. In 996 he croſſed the Alps, reduced Milan, where he received the Lombard crown, and proceeding to Rome, filled the pontifical chair, which was become vacant, with a relation of his own, by the name of Gregory V., by whom, in return, he was crowned emperor. He pardoned Creſcentius, quieted the diſturbances at Capua and Benevento, and then reviſited the Lombard cities on his return to Germany. On his arrival at Modena, he gave a ſtriking proof of what was denominated, in thoſe days, a love of juſtice, upon the empreſs Mary, daughter of the king of Arragon, who, having been repulſed in her criminal advances to the count of that place falſely accuſed him of an attempt upon her honour. Otho, paying credit to the charge, had put the count to death, but his widow demanding juſtice, having proved the innocence of her huſband, Mary was ordered to be burnt alive, and the emperor devoted a large ſum of money to be paid for the benefit of the widow. Such is the ſtory of the time, which is entirely diſcredited by many of the beſt hiſtorians; and others, who ſeem to concur in admitting the general fact, repreſent the empreſs as having only been diſgraced, and her detection in ſome criminal act is, perhaps, not very improbable.

As ſoon as Otho had returned into Germany, and begun to make ſome neceſſary regulations, he received the vexatious intelligence that Creſcentius, having obtained the conſulſhip in Rome, had expelled pope Gregory, and filled his place with another, who had aſſumed the name of John XVI. The emperor inſtantly marched with all poſſible expedition into Italy, made himſelf maſter of Rome, and treated the two uſurpers with extraordinary ſeverity: for the anti-pope, after having been deprived of his eyes and his noſe, in the moſt cruel manner, was hurled from the top of the caſtle of St. Angelo; and Creſcentius, after being expoſed to public deriſion, and put to the torture, was hanged upon a very high tree, together with twelve of his adherents. He re-eſtabliſhed Gregory, and publiſhed a decree, declaring, that for the future the Germans alone ſhould have the privilege of electing a Roman emperor. In the year 1000, at the ſolicitation of the duke Boleſlaus, he erected Poland into a kingdom, to be held as a fief of the empire, on condition of homage. Shortly after this event, Otho was again called into Italy to repel an invaſion of the Saracens, and to cruſh a freſh revolt of the turbulent Romans. His exertions againſt the Saracens were attended with complete ſucceſs, but the Romans openly refuſed to ſubmit to his authority, and while he was aſſembling an army to revenge this inſult, he was poiſoned by a widow, whom he is ſaid to have ſeduced under a promiſe of marriage. He died at Palermo in 1002, in the thirtieth year of his age, and the eighteenth of his reign. In his laſt moments, he fixed upon Aix-la-Chapelle as the place of his ſepulture. Otho III. is reckoned to have had many great qualities, and he governed with vigour and ſucceſs. In common with his father and grandfather, he was very liberal to the church, and it is ſaid that two-thirds of the eccleſiaſtical benefices in Germany were granted by the firſt three Othos.

Otho IV., emperor of Germany, was duke of Saxony, of the houſe of Brunſwick, when, on the death of the emperor Henry IV., in 1197, Philip, duke of Swabia, his brother, in quality of guardian to his minor nephew, Frederic, aſſumed the adminiſtration of the empire. A party, inſtigated by pope Innocent III., roſe in oppoſition to the houſe of Swabia, and elected Otho king of the Romans. He was at this time in Poitou, with his uncle Richard I. of England, and haſtening into Germany, he collected forces, and repaired to Aix-la-Chapelle, where he was crowned by the archbiſhop of Cologne. On the other ſide, the partizans of the Swabian family conferred the ſame honour upon Philip, and a civil war deſolated all Germany. Otho loſt a powerful ſupporter on the death of king Richard; for John, who ſucceeded him, abandoned the intereſts of his nephew. In 1205, Otho took refuge in England, and Philip was left without a rival; but while he was treating for a reconciliation, and employing himſelf in gaining the affections of his ſubjects, he was baſely murdered by a private hand in 1208. On this event Otho ſo ingratiated himſelf with the clergy and pope, that Innocent invited him into Italy to receive the imperial crown at his hands. In 1209 he croſſed the Alps, and was crowned king of Lombardy at Milan, and emperor at Rome. In the following year he made incurſions into the territories of Frederic, king of the Two Sicilies, although that prince was under the protection of the holy ſee. Innocent, enraged at this proceeding, fulminated an excommunication againſt him, which he cauſed to be publiſhed and generally circulated through the empire. He was depoſed, and Frederic, the ſon of the former emperor, Henry VI., placed on the throne in his ſtead. Otho, without heſitation, returned to Germany, aſſembled his friends, and commenced hoſtilities againſt the oppoſite party: he was, however, ſoon defeated, and gladly retired to Brunſwick, where he paſſed four years in a private condition, devoting himſelf to exerciſes of devotion, and then died, A.D. 1218. Univer. Hiſt.

Otho, a celebrated chronicler of the twelfth century, the ſon of Leopold, marquis of Auſtria, and Agnes, daughter of the emperor Henry IV., was educated for the eccleſiaſtical profeſſion, and was appointed, in very early life, by his father, provoſt of the college which he had founded at Newenburg, in Auſtria. He afterwards ſpent ſome years in his ſtudies at Paris, and then became abbot of a monaſtery of Ciſtertians at Moribond, in Burgundy. In 1138 his brother, Conrad III., created him biſhop of Frienjen, in Bavaria. He afterwards accompanied that prince in his expedition to the Holy Land, and was frequently conſulted by him in his affairs, as he was alſo by Frederic Barbaroſſa, who was his nephew. Otho died at Moribond in 1158. He is ſaid to have been the firſt, or, perhaps, more probably, among the firſt of the German prelates who were verſed in literature, and acquainted with the Ariſtotelian philoſophy. It is, however, as a hiſtorian that his memory has been preſerved. He compoſed a chronicle from the creation to his own times, in ſeven books: another book is added relating to antichriſt, and the end of the world: alſo, in two books, a narrative of the actions of Frederic Barbaroſſa. Theſe writings were firſt made public by John Caſpinian, and the chronicle was afterwards publiſhed, with the addition of more than 50 chapters, by Urſtitius of Baſil, in his Hiſtory of celebrated Germans. It is alſo contained in the collections of Piſtorius and Muratori.

OTHOMAN. See Ottoman.

OTHONE, *οθονη* and *οθονιον*, among the ancients, a kind of linen garment worn by women.

OTHONI, a word uſed by chemical writers for what they otherwiſe call the *mercury of the philoſophers*, or *philoſophic ops*.

OTHONNA, the name given by ſome authors to a ſtone found in Egypt, and deſcribed to be always in ſmall pieces, and of the colour of poliſhed braſs: probably it is ſome ſpecies of the pyrites.

Othonna, in *Botany*, a name which occurs in Pliny,

and which is called οθονναι by Dioſcorides. The word is derived from οθονη, *a linen cloth*, or *napkin*, from the external downy or cottony clothing of ſome of the original ſpecies. Linn. Gen. 449. Schreb. 585. Willd. Sp. Pl. v. 3. 2371. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 276. Juſſ. Gen. 181. Lamarck Dict. v. 4. 664. Illuſtr. t. 714. Gærtn. t. 170. (Jacobæaſtrum; Vaill. Mem. Par. 1720. 15.)—Claſs and order, *Syngeneſia Polygamia Neceſſaria*. Nat. Ord. *Compoſitæ Diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* perfectly ſimple, of one leaf, obtuſe at the baſe, acute, equal, divided into eight or twelve ſegments. *Cor.* compound, radiated; *florets* of the diſk perfect, numerous, tubular, five-toothed, ſcarcely longer than the calyx: thoſe of the radius female, moſtly eight, or as many as the ſegments of the calyx, ligulate, lanceolate, longer than the calyx, three-toothed, reflexed. *Stam.* (in the perfect florets) Filaments five, capillary, very ſhort; anthers united into a cylindrical tube the length of the floret. *Piſt.* (in the perfect florets) Germen oblong; ſtyle thread-ſhaped, ſcarcely longer than the ſtamens; ſtigma cloven, ſimple: the female or ligulate florets differ only in having their ſtigma reflexed and larger. *Peric.* none, except the unchanged, permanent calyx. *Seeds* only in the female florets, ſolitary, oblong, naked or crowned. *Recept.* naked, dotted.

Obſ. In ſome ſpecies the ſeeds are crowned with down; in ſome the calyx is divided beyond the middle; in others it is only toothed, but the ſame ſhape or figure is obſervable in all.

Eſſ. Ch. Receptacle naked. Down generally none. Calyx of one leaf, divided, nearly cylindrical.

Obſ. When this genus was firſt eſtabliſhed by Linnæus, a number of plants were included in it, which are now referred to other places. Of thoſe which remain, and which have the calyx of one leaf, the moſt eſſential mark of *Othonna*, the following are examples. Profeſſor Willdenow has thirty-five ſpecies, and theſe are divided into two ſections; the firſt of which compriſes ſuch ſpecies as have cut or pinnate leaves; the ſecond, ſuch as have their leaves undivided, and toothed or entire.

* *Leaves cut or pinnate.*

O. *pectinata*. Wormwood-leaved African Ragwort. Linn. Sp. Pl. 1309. Curt. Mag. t. 306. (O. foliis pinnatifidis: laciniis linearibus parallelis; Mill. Dict. t. 194. f. 2.)—Leaves pinnatifid or pectinated, downy; the ſegments linear, toothed at the outer margin. Native of Africa and the Cape of Good Hope. It flowers with us in May and June, and was introduced into the gardens by Mr. Philip Miller in 1731. *Stem* ſhrubby, two or three feet high, much branched, covered with a hoary down. *Leaves* white with down, cut into many narrow ſegments, almoſt to the mid-rib; theſe ſegments are equal and parallel, having two or three teeth at their tips. *Flowers* on long, axillary ſtalks, towards the extremities of the branches, of a yellow colour. *Seeds* purple. Linnæus obſerves that the whole plant is often tomentoſe, and that the ſtem is ſcarred.

O. *pinnata*. Pinnated African Ragwort. Linn. Suppl. 387. Willd. n. 8. Sims in Bot. Mag. t. 768.—Leaves pinnatifid; the ſegments lanceolate, entire, decurrent.—A native of the Cape of Good Hope, flowering with us in May. This plant was conſidered by Linnæus, in his *Species Plantarum*, as a variety of *bulboſa*, from which however it was ſeparated, by Thunberg's advice, in the *Supplementum* of his ſon.—*Root* tuberous. *Stem* waved, almoſt proſtrate, ſlender. *Lower leaves* pinnated; upper undivided, obovate, obtuſe; all of them glaucous. *Flowers* terminal, yellow. It is remarked, in the Botanical Magazine, that this ſpecies has "a very particular manner of ſleeping, the petals being neatly rolled back every evening from the apex to the baſe, remain in this ſtate till morning, when they again expand."

O. *Athanaſiæ*. Fennel leaved African Ragwort. Linn. Suppl. 386. Jacq. Hort. Schoenbr. v. 2. 62. t. 242. (Jacobæa africana fruticans, foliis abrotani major; Volck. Hort. 225.) Leaves pinnate, thread-ſhaped. Calyx many-toothed.—Native of the Cape, flowering from December to February. *Stem* ſhrubby, round, ſcarred, erect, two or three feet high, branched, darkiſh brown, reſinous. *Leaves* numerous, much ſpreading, pinnate; their ſegments lanceolate, graſſy, or fennel-like. *Flowers* ſolitary, terminal, ſtalked, yellow, large, and handſome. The whole plant has a ſmell like turpentine.

O. *abrotanifolia*. Southernwood-leaved African Ragwort. Linn. Sp. Pl. 1310. (Jacobæa africana fruticans, foliis abrotani minor; Volck. Hort. 225. tab. ad finem.)—Leaves pinnate, much divided, linear. Joints of the ſtem villoſe.—Native of the Cape. It was cultivated by Miller in 1759, and flowers with us from January to March. *Stem* low and ſhrubby, branched. *Leaves* thick, like thoſe of Sampire, and cut into many narrow ſegments. *Flowers* ſolitary, terminal, on ſhort ſtalks, yellow.

** *Leaves ſimple, or undivided.*

O. *tenuiſſima*. Slender ſimple-leaved African Ragwort. Linn. Mant. 118. Willd. n. 32. Jacq. Hort. Schoenbr. v. 2. 61. t. 239.—Leaves thread-ſhaped, fleſhy. Stem ſhrubby.—Native of the Cape, flowering in March and April.—*Stems* ſhrubby, erect, branched, four feet in height, ſcarred. *Leaves* ſcattered, ſeſſile, linear, acute, entire, fleſhy, hairy when young, ſmooth when old. *Flowers* ſolitary, on axillary ſtalks, yellow. Linnæus well gueſſed the genus by the habit; ſee *Mant.*

Willdenow enumerates twenty-two ſpecies under this ſection of the genus, and thirteen under the firſt. Jacquin makes *Cineraria perfoliata* of Linnæus an *Othonna*, but we are inclined to think with Willdenow that it ſhould not be removed from the former genus. *O. filicaulis* of Jacquin does not appear to be generically diſtinct from *Cineraria perfoliata*.

Othonna, in *Gardening*, contains plants of the ſhrubby, exotic, evergreen kind, of which the ſpecies cultivated are; the bulbous African ragwort (O. bulboſa); the wormwood-leaved African ragwort (O. pectinata); the ſouthernwood-leaved African ragwort (O. abrotanifolia); the buck's-horn-leaved African ragwort (O. coronopifolia); the ſtock-leaved African ragwort (O. cheirifolia); and the tree African ragwort (O. arboreſcens.)

Method of Culture.—All theſe plants may be increaſed by planting ſlips and cuttings of the young ſhoots or branches during the ſummer months, in pots filled with fine earth, plunging them in an old tan hot-bed under glaſſes, carefully ſhading them from the heat of the ſun till perfectly rooted; their ſtriking may be promoted by being covered with ſmall glaſſes. When they are become well rooted, they ſhould be removed with balls into ſeparate pots filled with loamy mould, placing them in a ſheltered ſhady ſituation till autumn.

They ſhould be preſerved in a good greenhouſe in the winter, having as much free air as poſſible, and in the ſummer placed in a ſheltered warm ſituation.

The fifth ſort may ſometimes be preſerved in the open ground in ſuch ſituations.

O T I

They produce variety among other potted plants of the greenhouſe kinds.

OTHUMA, in *Geography*, a town of Arabia, in the province of Yemen; 80 miles N.N.E. of Mocha. N. lat. 54° 32′. E. long. 43° 57′.

OTIBAR, a town of Spain, in the province of Granada; 12 miles W.N.W. of Motril.

OTIOSI, in the *Hebrew Cuſtoms*. The learned are exceedingly divided about the *decem otioſi, ten idle perſons*, ſpoken of in the Jewiſh ſynagogues.

Some ſay they were the three preſidents and the ſeven readers; others, that they were ten perſons hired to attend conſtantly at the ſynagogue, becauſe, without the number ten, it could be no regular ſynagogue, or legal aſſembly; ſo that the decem otioſi were ten idle folks kept in pay, to form by their preſence a legal ſynagogue or quorum.

Vitringa, in his Archi-Synagoga, refutes this opinion; and will have the otioſi to have been ten directors or officers in the ſynagogue.

He ſhews, that each ſynagogue had its directors; that the number was greater or leſs, according to the dignity of the ſynagogue; that the ſmalleſt had at leaſt two; that, from the earlieſt times, each ſynagogue had its chief, called *archi-ſynagogus*, who had two colleagues, to be preſent at the ceremonies, and other acts of religion, and to take care every thing were done with decency; but that the archi-ſynagogus reſerved to himſelf the power of teaching: that, beſides theſe three, the archi-ſynagogus named ſeveral readers, who read in the ſynagogue every ſabbath, and that theſe made the decem otioſi of the ſynagogue; ſo called, becauſe, being diſengaged from all other employment, their whole attendance was on divine ſervice.

OTIS, the Buſtard, in *Ornithology*, a genus of birds of the order Gallinæ: of which the generic character is; bill ſubconvex; noſtrils oval, pervious; tongue bifid, pointed; feet formed for running; three-toed, tall, naked above the thighs. Of this genus there are eleven ſpecies deſcribed in Gmelin, and nine by Latham. We ſhall, as uſual, follow the arrangement of the former writer, noticing, as in other articles, thoſe that belong to our own country by means of an aſteriſk.

Species.

*Tarda; Great Buſtard. Wave-ſpotted with black and rufous, beneath whitiſh, head of the male, and throat on each ſide, creſted. This bird is found in the plains of Europe, Aſia, and Africa, but has never been obſerved in America. In England it is met with on Saliſbury Plain, and in the wolds of Yorkſhire; it was formerly ſeen in flocks of forty or fifty. It is the largeſt of Britiſh land birds, weighing from twenty-five to thirty pounds. It runs with great rapidity, ſo as to eſcape the purſuit of common dogs, but falls ſpeedily a victim to the grey-hound, which often overtakes it before it has the power to commence its flight, the preparation for which, in this bird, is ſlow and laborious. The female lays her eggs on the bare ground, never more than two in number, in a hole ſcratched out by her for the purpoſe; and if theſe are touched or ſoiled during her occaſional abſence, ſhe immediately abandons them. The male is diſtinguiſhed by a large pouch, beginning under the tongue, and reaching to the breaſt, capable of holding ſeven quarts of water. This is uſeful to the female during incubation, and to the young before they quit their neſt; and it has been obſerved to be eminently advantageous to the male-bird himſelf, who, on being attacked by birds of prey, has often diſcomfited his enemies by the ſudden and violent diſcharge of water upon them. Theſe birds are ſolitary and ſhy, and feed principally upon graſſes, worms, and grain. They were formerly much hunted by dogs, and conſidered as ſupplying no unintereſting diverſion. They ſwallow ſtones, pieces of metal, and other hard ſubſtances.

Arabs; Arabian Buſtard. Ears with erect creſts. It inhabits Aſia and Africa, and is the ſize of the laſt.

*Tetrax; Little Buſtard. The head and throat of this ſpecies are ſmooth. It inhabits ſouthern Europe and Aſia; is rarely found in England; is ſeventeen inches long; the eggs are of a ſhining green; the fleſh is blackiſh. The bill is grey-brown; crown black, with rufous bands; temples and chin reddiſh-white, with ſmall dark ſpots; neck of the male black, with a white collar; body above varied with black, rufous, and white; beneath and outer edge of the wings white. It is ſhy and cunning: if moleſted it will fly two hundred paces, and run ſo faſt that a man cannot overtake it.

Afra; White-eared Buſtard. It inhabits the Cape of Good Hope, and is twenty-two inches long. In the male the bill and legs are yellow; the crown cinereous; the wings with a large blotch; neck behind, and thighs above the knees, with a white collar; fourteen tail-feathers; the female is cinereous, and her thighs and belly black.

Bengalensis; Indian Buſtard. Black; area of the eyes brown; back, rump, and tail, ſhining brown. It inhabits, as its name imports, Bengal, and is thirteen inches long.

Aurita; Paſſarage Buſtard. This ſpecies is black; the body above reticulate with brown; the hind head has four capillary feathers on each ſide, rhombic at the tips; the ſpot on the wings and ears white. It inhabits India, and is the ſize of O. tetrax. The bill is of a whitiſh-brown; the legs are yellowiſh.

Houbara; Ruffed Buſtard. Yellowiſh, ſpotted with brown; feathers of the neck long, whitiſh, with black ſhafts; the quill-feathers black, with a white ſpot in the middle. It inhabits Africa and Arabia, and is the ſize of a capon.

Rhaad. This is an Arabian bird; the hind head of the male has a black-blue creſt; the head is black; body above, and wings yellow, ſpotted with brown; the belly is white; the tail is browniſh, with tranſverſe black ſtreaks. The bill and legs robuſt.

Indica; White-chinned Buſtard. The upper part is ferruginous, waved with white and black, beneath whitiſh; chin white; crown, area of the eyes, and a ſtreak on each ſide the head, is black. It inhabits India, and is the ſize of the next ſpecies. The legs are browniſh.

*Oedicnemus; Thick-kneed Buſtard. This ſpecies is greyiſh; the two firſt quill-feathers are black, white in the middle; bill ſharp pointed; legs cinereous. It inhabits Europe, Aſia, and Africa; feeds in the night on worms, caterpillars, and reptiles; breeds in holes, or among ſtones on the bare ground; the eggs are of a copper colour, ſpotted with darker red; makes a piercing ſhrill cry, and migrates. The bill is black; legs greeniſh-yellow; lower eye-lid naked, pale yellow; above and beneath the eyes there is a yellow line; from the bill under the eyes to the ears there is a brown line; the knees are thick, as if ſwollen; belly and thighs white.

Chilensis. Head and throat ſmooth; body white; crown and tail-feathers cinereous; primary quill-feathers black. It inhabits Chili, is even larger than the O. tarda; is gregarious, and feeds on herbs; it is thought not to belong to this genus. The tail, which conſiſts of eighteen feathers, is ſhort; it has four very thick toes.

OTISFIELD, in *Geography*, a town of America, in Cumberland county and ſtate of Maine; E. of Bridgetown, and containing 450 inhabitants.

OTITES DIGITUS, the *ear-finger*, a name given by authors to the finger next the little one.

OTITIS, from ους, *the ear*, inflammation of the ear.

OTLEY, in *Geography*, a market town in the upper diviſion of the wapentake of Skirack, liberty of Cawood, Wiſtow, and Otley, and Weſt Riding of Yorkſhire, England, is ſituated under a cliff called Chevin, near the ſouth bank of the river Wharfe. This town was formerly remarkable for the great quantity of oats cultivated in its neighbourhood, and ſold at the market, which is held on Friday, and ſtill affords a very plentiful ſupply of that ſpecies of grain. Here was an hoſpital for lepers in the time of Edward II., who were bound to keep the bridge over the Wharfe in repair. No veſtiges of this building now remain, neither can any traces be diſcovered of the ancient palace of the archbiſhops of York, to whom the manor of Otley was given by king Athelſtan. In 1673 this town ſuffered ſeverely from an inundation, which ſpread to a conſiderable diſtance over the adjoining country. Here is a free grammar-ſchool, founded in 1611. The church is a large and rather elegant edifice, and contains a great variety of monumental erections in honour of the families of Fairfax, Fawkes, Vaſaſour, Palmes, and Pulleyn. From the population returns of 1811, Otley appears to contain 573 houſes, and 2602 inhabitants.

The vicinity of this town preſents to the eye a very rich and beautiful proſpect, particularly when ſurveyed from the ſummit of the Chevin. It abounds with gentlemen's ſeats, among which Newhall, Weſton, Farnley-Hall, Denton Park, and Harewood-Houſe, are the principal. The latter, the chief ſeat of lord Harewood, is one of the moſt magnificent manſions in England. It was erected by the late lord, who laid the foundation in 1760. The ſtyle of the architecture is Corinthian; and the whole is fitted up ſuitably to its external grandeur. The extenſive pleaſure grounds and gardens were laid out by the juſtly celebrated Browne. Near this manſion may be ſeen the ancient church of Harewood, rendered truly venerable by containing the tomb of that illuſtrious and virtuous judge, ſir William Gaſcoigne, of Gawthorpe, who committed to priſon the then prince of Wales, afterwards Henry V., for offering inſult to him on the bench. The ruins of the caſtle are ſeated on a lofty eminence overlooking the Wharfe. Theſe are very extenſive, covering above an acre of ground, but from their extremely dilapidated condition, it is impoſſible to form a correct idea of the conſtruction and appearance of this immenſe pile in its priſtine ſtate. Farnley-Hall, the ſeat of Walter Fawkes, eſq. is about three miles north of Otley, and is juſtly ranked among the fineſt manſions of the county, on account of the ſcale of the houſe, the ſtyle in which it is fitted up, its ſuperb and valuable collection of paintings and drawings, and for the natural character of the ſurrounding country. Its preſent poſſeſſor has diſplayed, on many occaſions, a refined taſte, and ſound political principles. Beauties of England, &c. vol. xvi. Yorkſhire, by J. Bigland.

OTMARSCH, a town of Holland, in the department of Overiſſel, ſeated on the river Dinckel; nine miles N. of Oldenzeel.

OTODINI, in *Ancient Geography*, a people of Britain, N.E. of the Brigantes, who inhabited the countries now called Northumberland, Merſe, and the Lothians. As the Otodini are not mentioned by any of the Roman hiſtorians, but only by Ptolemy, it is uncertain whether they formed a diſtinct, independent ſtate, or were united with the Brigantes. They were, however, a conſiderable people and poſſeſſed a long tract of the ſea-coaſt, from the river Tine to the Firth of Forth. Their name is derived by Baxter from the old Britiſh words "Ot o dineu," which ſignify a high and rocky ſhore, deſcriptive enough of their country. They were probably reduced by Agricola at the ſame time with their more powerful neighbours the Brigantes: but as they lived without the walls of Severus, they were, like the reſt of the Mæatæ, engaged in frequent revolts. In the moſt perfect ſtate of the Roman government in this iſland the country of the Otodini made a part of the Roman province called Valentia, which comprehended all that large tract between the two walls. As this province was never long together in the peaceable poſſeſſion of the Romans, they had but few ſtations in the country of the Otodini, except thoſe on the line of the wall of Severus. Beſides theſe, there were two or three Roman towns without the wall, ſituated on or near the military way which ran through their country into Caledonia, which are mentioned both by Ptolemy, and in the Itinerary of Antoninus. Theſe towns were Barmenium, now Riecheſter, and Curia or Corſtupitum, now Corbridge. Between theſe two towns, and at a little diſtance from the military way, at a place now called Riſingham, there are very conſpicuous veſtiges of a Roman ſtation; which, from the inſcription of an altar found there, appears to have been named Habitancum.

OTOGAMIES, in *Geography*, a tribe of Indians in the N.W. territory, who inhabit between the lake of the Woods and Miſſiſippi river. Its number of warriors is 300.

OTOMACS, or OTOMAQUES, ſavages of America, on the Orinoco. For an account of them, ſee ORONOOKO.

OTOMO, in *Ornithology*, the name of a bird of the lagopus kind, called alſo *colmeſtre*, and by the Germans *ſteinhum*, that is, *ſtonehen*. It is of the bigneſs of a tame pigeon; its belly and wings are white, with only a very few browniſh feathers; its head, neck, and breaſt are variegated with brown feathers, and the upper part of the neck with black and white; its beak is very ſhort and black, and it has fine red granulated membranes over its eyes; its tail is principally black, but is variegated with brown and white; and its legs and feet are feathered to the ends of the toes.

Mr. Ray is of opinion, that this is the ſame ſpecies of bird with the common white lagopus, it being no way different but in colour, and thoſe birds being ſaid to change colour in the ſummer months. It is caught in the mountains of Germany, and is a very delicate bird for the table.

OTOORACITE, in *Geography*, a ſmall iſland in the South Pacific ocean, near the eaſt coaſt of Otaheite.

OTOPLATOS, in *Surgery*, a fetid diſcharge from behind the ears.

OTOPUOSIS, from ους, *the ear*, and πυον, *pus*, a purulent diſcharge from the ear.

OTOQUE, in *Geography*, a ſmall iſland on the weſt coaſt of New Mexico, in the bay of Panama; 30 miles S.S.W. of Panama. N. lat. 8° 30′. W. long. 80° 20′.

OTOROWA, a town of the duchy of Warſaw; 16 miles W. of Poſen.

OTORRHŒA, in *Surgery*, from ους, *the ear*, and ῥεω, *to flow*, a diſcharge of blood, or bloody matter, from the ear.

OTOULINGOW, in *Geography*, a town of Chineſe Tartary. N. lat. 43 54′. E. long. 128° 16′.

OTRAHARMANA, LA, a ſmall iſland in the Eaſt Indian ſea, near the weſt coaſt of Luçon. N. lat. 15° 55′. E. long. 120 6′.

OTRANTO, a province of Naples, bounded on all ſides,

ſides, the weſt excepted, by the ſea. On the weſt it is joined to Bari. It is about 60 miles in length, and from 20 to 25 in breadth. Its principal productions are olives, figs and grapes. As a guard againſt the incurſions of the corſairs, towers are erected at ſmall diſtances along the coaſt. Beſides Lecce, whence it is ſometimes called "the country of Lecce," and Otranto, the principal towns are Tarento, Brindiſi, Matera, Caſtro, Gallipoli, Motala, Sta. Maria de Leuca, Aleſſano, Ugento, Nardo, Oſtuni, and Caſtellaneta.—Alſo, a city and ſea-port of Naples, and capital of the above province. It was a Roman colony, and erected into an archbiſhopric in the 16th century. It is ſeated on a rocky iſland, and joined to another iſland by a bridge, which, by another bridge, communicates with the continent. It is ſurrounded by walls and ramparts, and defended by a citadel on a rock. The harbour is good, and the trade conſiderable. It is the ſee of an archbiſhop; 94 miles S.E. of Bari. N. lat. 40° 30'. E. long. 18° 20'.

OTRAR, or FARAL, a town of Turkeſtan, on the Arſch; formerly a place of great importance and conſiderable trade. After a brave defence, it was taken by Jenghis Khan. The celebrated Timur Bec died here; 55 miles W. of Taraz.

OTRAU, a town of Moravia, in the circle of Prerau; 10 miles N.E. of Prerau.

OTRICOLI, a town of Italy, in the Sabina, near the Tiber, formerly the ſee of a biſhop. In this place are the ruins of a theatre and other magnificent buildings; 24 miles S.W. of Spoleto.

OTROKOTSKIFORIS, FRANCIS, in *Biography*, an Hungarian, who completed his ſtudies at Utrecht, and became miniſter in his native country. He afterwards renounced the Proteſtant religion, and obtained ſome preferment in the ſtate. He died at Tirnau in 1718. His works are, 1. "Origines Hungaricæ," 2 vols. 8vo. 2. "Antiqua Religio Hungarorum vere Chriſtiana et Catholica," 8vo.

OTSEGO, in *Geography*, a county of New York, on the ſouth ſide of Mohawk river; bounded north by Herkemer county, eaſt by Schoharie, ſouth by Delaware, and weſt by Chenango. This county is interſected by the headwaters of the Suſquehannah, and the Cookquago branch of the Delaware. It contains 1788 inhabitants. The courts are held at Cooperſtown, in the townſhip of Otſego. In 1791, when the county was thinly ſettled, 300 cheſts of maple ſugar, at 400 lbs. *per* cheſt, were manufactured here. —Alſo, a townſhip and lake, in the above county. The townſhip was taken from Unadilla, and incorporated in 1794. On the eaſt the townſhip includes lake Otſego, which ſeparates it from Cherry valley. The lake is the head of Suſquehanna river, and is about nine miles long, and ſomewhat more than a mile wide. The lands on its banks are good, and eaſily cultivated. The townſhip contains 4224 inhabitants.

OTSKE, a town of Turkiſh Armenia; 20 miles N.W. of Akalziké.

OTT, JOHN HENRY, in *Biography*, a learned Swiſs divine, was born in the canton of Zurich in the year 1617. He received the early part of his education at Zurich, and in 1635 was ſent to purſue his ſtudies at Lauſanne. From thence he went to Geneva and Groningen; and in the latter place diſtinguiſhed himſelf by his great proficiency under the inſtructions of Gomar and Alting. He then ſpent five years at Leyden and Amſterdam, chiefly in the ſtudy of the Oriental languages. After this he took a tour to England and France; and upon his return to his native country, he was preſented with a good living, which he ſerved 25 years. In 1651 he was nominated to the profeſſorſhip of eloquence at Zurich; in 1655, to that of Hebrew; and in 1668, to that of eccleſiaſtical hiſtory. He died in 1682, leaving behind him a high reputation for various learning, and a great number of works, which were highly eſteemed on account of the erudition diſplayed in them. Of theſe we may mention a treatiſe "On the Grandeur of the Church of Rome;" "Annals relating to the Hiſtory of the Anabaptiſts;" "A Latin Diſcourſe in favour of the Study of the Hebrew Language;" "A Latin Treatiſe on Alphabets, and the Manner of Writing in all Nations." He had a ſon, John Baptiſt Ott, born in 1661, who acquired great celebrity by his knowledge of the Oriental languages and antiquities. He was paſtor of a church at Zollicken, and afterwards profeſſor of Hebrew at Zurich. In 1715 he was promoted to the archdeaconry of the cathedral in that city. He was the author of ſeveral works of conſiderable reputation: as, "A Diſſertation on Vows;" "A Letter on Samaritan Medals, addreſſed to Adrian Reland:" both theſe are written in the Latin language; a treatiſe in German, "On the Manuſcript and printed Verſions of the Bible before the Era of the Reformation;" and "A Diſſertation on certain Antiquities diſcovered at Klothen, in 1724." Moreri.

OTTA, in *Geography*, a town of Portugal, in Eſtramadura; 24 miles N.N.E. of Liſbon.

OTTACANO, a town of Naples, in the province of Lavora; 11 miles E. of Capua.

OTTANI, GAETANO, in *Biography*, a tenor-ſinger in the ſervice of the king of Sardinia, who, in 1770, with an excellent tenor voice, ſung with taſte, and in a pleaſing manner. Though the opera-houſe was ſhut, and we had not an opportunity of hearing him on the ſtage, we heard him in private ſing two or three airs in different ſtyles, which diſcovered him to be a maſter of the art he profeſſed. He likewiſe was a good painter in the manner of Claude Lorrain, and Du Vernet, and was ſometimes employed by his Sardinian majeſty as a painter.

OTTATI, in *Geography*, a town of Naples, in Principato Citra; 10 miles S.W. of Cangiano.

OTTAVA, a town of Naples, in the province of Bari; 11 miles S.S.E. of Monopoli.

OTTAWA, a river which riſes in the ſouth part of Bohemia, and runs into the Muldau, 12 miles E. of Blatna.

OTTAWAS, or UTAWAS, called alſo *Grand River*, a river of Canada, which is the moſt important of all the tributary ſtreams of the great river St. Lawrence, iſſues from various lakes towards the centre of Canada, and falls into the St. Lawrence about 30 miles above Montreal; forming, by its confluence with that river, "Le Lac de deux Montagnes et le Lac St. Louis," *i. e.* the lake of the two mountains, and the lake of St. Louis, in which are ſeveral iſlands. The water of the Utawas river is remarkably clear, and of a bright greeniſh colour; whilſt that of the St. Lawrence, on the contrary, is muddy, owing to its paſſing over deep beds of coral for ſome miles before it enters into lake St. Louis. For a conſiderable way down the lake, the waters of the two rivers may be plainly diſtinguiſhed from each other. At the mouth of the Utawas river is ſituated the iſland of Perot, about 14 miles in circumference, the ſoil of which is fertile, and well cultivated. The North-Weſt Company principally carries on its fur-trade by the Utawas river. For this purpoſe they make uſe of canoes, formed of the bark of the birch tree; ſome of which are conſtructed upon ſuch a large ſcale, that they are capable of containing two tons; but they ſeldom put ſo much in them, eſpecially

eſpecially in this river, as it is in many places ſhallow, rapid, and full of rocks, and contains no leſs than 32 portages. The canoes are navigated by the French Canadians, who prefer this employment to that of cultivating the ground. Having aſcended the Utawas river for about 280 miles, which it takes them about 18 days to perform, they then croſs by a portage into lake Niſpiſſing; and from this lake, by another portage, they get upon French river, that falls into lake Huron on the north-eaſt ſide; then coaſting along this laſt lake, they paſs through the ſtraits of St. Mary, where they have another portage into lake Superior; and coaſting afterwards along the ſhores of lake Superior, they come to the Grand Portage on the north-weſt ſide of it; from hence, by a chain of ſmall lakes and rivers, they proceed on to the Rainy lake, to the lake of the Woods, and for hundreds of miles beyond it, through lake Winnipeg, &c. The canoes, however, which go ſo far up the country, never return the ſame year: thoſe intended to bring back cargoes, immediately ſtop at the Grand Portage, where the furs are collected ready for them by the agents of the company. At the Grand Portage, and along that immenſe chain of lakes and rivers which extend beyond lake Superior, the company has regular ports, where the agents reſide; and they have alſo eſtabliſhed trading ports within 500 miles of the Pacific ocean. Weld's Travels through Lower Canada, &c. vol. i. See Fur.

Ottawas, a tribe of Indians who inhabit the eaſt ſide of lake Michigan, 21 miles from Michillimackinack, in Wayne county or territory. Their hunting grounds lie between lakes Michigan and Huron. About 30 years ago they could furniſh 200 warriors. A tribe of them alſo lived near St. Joſeph's, and had 150 warriors. Another tribe lived with the Chippewas, on Saguinan bay, who together could raiſe 200 warriors. Two of theſe tribes, lately hoſtile, ſigned the treaty of peace with the United States, at Greenville, Aug. 3, 1795. In conſequence of lands ceded by them to the United States, government has agreed to pay them in goods 1000 dollars a-year for ever.

OTTENDORF, a town of Germany, in the duchy of Bremen, capital of a ſmall county called Hadeln, on the river Meden; 24 miles N. of Stade. N. lat. 53° 50'. E. long. 8° 53'.

OTTENGRUN, a town of Saxony, in the Vogtland; 6 miles S.W. of Oelſnitz.—Alſo, a town of Germany, in the principality of Culmbach; 4 miles N. of Munahberg

OTTENHEIM, a town of Auſtria, on the north ſide of the Danube; 5 miles W.N.W. of Lintz.

OTTENSCHLAG, a town of Auſtria; 7 miles S. of Zwetl.

OTTENSTAIN, a town of Auſtria; 8 miles E. of Zwetl.

OTTENSTEIN, a town of Germany, in the biſhopric of Munſter; 25 miles W.N.W. of Munſter.

OTTER, John, in *Biography*, profeſſor of Arabic at Paris, was born at Chriſtianſtadt in Sweden, where his father had amaſſed conſiderable property. In 1724 he was ſent to the high ſchool at Lund, where he alſo applied himſelf to natural philoſophy and theology; and here, by intercourſe with perſons of the Catholic perſuaſion, he began firſt to feel ſerious doubts with regard to the reformation introduced by Luther, and at length abjured the Lutheran tenets; and the count de Bro[illegible]as, French ambaſſador at the Swediſh court, reſolved to ſend this new convert to France. He was admitted into the ſeminary at Rouen, and, after a reſidence of three years, was called to Paris by cardinal Fleury, who gave him an appointment in the poſt-office; a ſituation for which he was exceedingly well qualified, by a very extenſive knowledge of modern languages. Having recommended himſelf, by his talents and aſſiduity, to the notice of count Maurepas, that nobleman determined to ſend him to the Eaſt, in order that he might make himſelf maſter of the Oriental languages, and, at the ſame time, diſcover the beſt means of reviving the French trade in Perſia. He accordingly embarked at Marſeilles, in January 1734, and arrived at Conſtantinople in March. His principal object, while in this capital, was to learn the Turkiſh and Arabic languages: for that purpoſe, he frequented the company of the moſt learned men in that city, and particularly attached himſelf to Ibrahim Effendi, known as well by his literary labours, as by the eſtabliſhment of a printing-office at Conſtantinople. Having attained a good knowledge of the languages referred to, he felt himſelf in a condition to proceed to Perſia, which he did in December 1736. After a journey of eight months, he reached Iſpahan, which exhibited a moſt melancholy ſpectacle, having been reduced almoſt to a heap of ruins by the fury of the Afghans, who, in the midſt of a bloody war, had nearly over-run the empire. The ſituation of the country, at that period, deterring Otter from making any attempts towards the re-eſtabliſhment of the French trade in Perſia, he devoted himſelf to the ſecondary object of his journey, *viz.* the acquiring of the language. In 1739 he ſet out for Buſſorah, on the Perſian gulf, where he concluded a commercial treaty with the pacha of Bagdad, and where he reſided nearly four years, firſt in a private capacity, and afterwards as conſul of the French nation. The commotions which had agitated Perſia ſpread at length to Buſſorah; and in 1741, the ſpirit of inſurrection roſe to ſuch a height, that the neighbouring Arabs, throwing off all reſtraint, appeared in a ſtate of open rebellion. For two months they kept the town completely blockaded. Otter participated in the general diſtreſs, but the terror of the ſituation did not prevent him from purſuing the ſtudy of the languages. With the help of a preceptor, he began a tranſlation of the New Teſtament into the Turkiſh language, for the uſe of the Chriſtians in that neighbourhood; and he had nearly completed the work, when he received orders, in the month of May 1743, to return to France, which he did by the way of Conſtantinople. On his return, after an abſence of ten years, he publiſhed, under the patronage of count Maurepas, a work entitled "Voyages en Turquie et en Perſe, avec une Relation des Expeditions de Thamas Kouli Khan, Paris, 1748." This work, beſides a great many uſeful obſervations in regard to the names and ſituations of places, determined by Arabian aſtronomers, remains of antiquity, natural hiſtory, and accounts of the manners and cuſtoms of the Perſians, and other eaſtern nations, contains a ſhort account of the revolution effected in Perſia by the celebrated Kouli Khan, with ſome anecdotes of his life. (See Kouli Khan.) Soon after the return of M. Otter to France, he was appointed by count Maurepas to be interpreter of the oriental languages in the king's library; an office which enabled him to render the knowledge that he had acquired during his long travels of more utility to literature. He began to compile a view of the political changes produced by the followers of Mahomet, from the origin of their religion to the preſent time; taking as a foundation of his work the writings of the celebrated Noviari, an hiſtorian of the 14th century, who is reckoned one of the moſt authentic ſources of information on that ſubject. In 1746, after completing a part of this undertaking, he was appointed Regius profeſſor of Arabic; and in 1748 he was elected a member of the Academy of Inſcriptions. Soon after his admiſſion,

admiſſion, he read "A Diſſertation on the Conqueſt of Africa by the Arabs;" and this was to have been followed by another of the conqueſt of Spain, but in conſequence of his premature death, the work remained unfiniſhed, as did ſeveral others which he had projected. He died at Paris, in 1749. Otter was a man of great learning and integrity, mild in his manners, and of a modeſt diſpoſition. Gen. Biog.

Otter, in *Geography*, an iſland in the North ſea, on the coaſt of Norway, at the mouth of Romſdal bay. N. lat. 62° 45′. E. long. 7° 9′.

Otter, a river of England, which runs into the ſea, about 5 miles E. of Exmouth.

Otter *Bay*, a bay on the S. coaſt of Newfoundland, between Bear and Swift bays, and near cape Ray.

Otter *Creek*, a river of America, in Vermont, which riſes in Bromley, and purſuing a northern direction about 90 miles, diſcharges itſelf into lake Champlain at Ferriſburg, receiving in its courſe about fifteen ſmall tributary ſtreams. It has ſeveral falls, between which the water is navigable for the largeſt boats. Veſſels of any burden may go up to the falls at Vergennes, 5 miles from its mouth. The head of this river is not more than 30 feet from Batten Kill, which runs in a contrary direction and falls into Hudſon's river.—Alſo, a ſmall ſtream, which runs into Kentucky river, E. of Boonſborough.

Otter, *Peaks of*, the higheſt mountains on the Blue Ridge of Virginia, which, meaſured from their baſes, are ſuppoſed to be more lofty than any others in North America. The principal peak, according to Mr. Jefferſon, is about 4000 feet in perpendicular height.

Otter's *Head*, a lofty rock on the N. ſhore of lake Superior. N. lat. 48° 4′. W. long. 85° 55′.

Otter, in *Zoology*. See Mustela.

Otter, *Hunting*. See Hunting.

OTTERBACH, in *Geography*, a river of France, which riſes near Weiſſemburg, and runs into the Rhine, about 10 miles above Germerſheim.

OTTERBERG, a town of France, in the department of Mont Tonnerre, and chief place of a canton, in the diſtrict of Kaiſerſlautern; 5 miles N. of Kaiſerſlautern. The place contains 1374, and the canton 5359 inhabitants, in 20 communes.

OTTERPIKE, in *Ichthyology*, the name of a large ſpecies of the *draco marinus*, or ſea-dragon, called in Engliſh the *weaver*: it is not much larger than the weaver, but is of a great variety of beautiful colours; and, inſtead of the yellow ſide-lines which that fiſh has, this has rows of large black ſpots. See Trachinus *Draco*.

OTTERSBERG, in *Geography*, a town of the duchy of Bremen, defended by a fort with four baſtions; 16 miles E. of Bremen. N. lat. 53° 9′. E. long. 9° 11′.

OTTERY St. Mary, a market town in the hundred of that name and county of Devon, England, is ſituated near the bank of the river Otter, at the diſtance of 12½ miles from the city of Exeter and 161 from London. It is a large, irregularly built town, and is chiefly ſupported by its manufactories of flannel, ſerge, and other woollen goods. The market day is Tueſday every week, and Carliſle ſtates there are fifteen fairs annually. Here is a grammar ſchool, formerly kept by the father of the poet Coleridge. The church is a ſpacious edifice, poſſeſſing many ſingularities in its conſtruction. On the north and ſouth ſides are ſquare towers, which open into the body of the church, and form two tranſepts, as in the cathedral at Exeter. Both theſe towers are ſurmounted by ſmall turrets and open battlements, and that on the north has likewiſe a ſmall ſpire in the centre. A chapel, erected by biſhop Grandiſon at the north-weſt corner of the building, diſplays a very richly ornamented ſpecimen of architecture, but this and almoſt every other part of the church has ſuffered much from neglect. The monuments are numerous, and many of them curious both with reſpect to deſign and execution. Cloſe to the church-yard ſtand ſome of the old collegiate houſes, belonging to a college which was founded here by the biſhop above mentioned, "for a warden, ten vicars, a maſter of muſic, two pariſh prieſts, eight ſecondaries, eight choriſters, and two clerks." In one of theſe buildings is a large hall, which Oliver Cromwell uſed as a convention room; and in Mill-ſtreet are the remains of the ancient manſion of the celebrated ſir Walter Raleigh. According to the late population returns (1811), the houſes in this town and parith are eſtimated at 587, and the inhabitants at 2880 in number. The petty ſeſſions for the hundred are held here.

Clyſt-houſe, lately built by lord Graves, occupies the ſcite of one of the ancient palaces of the biſhops of Exeter. It is a very noble edifice, and commands ſeveral rich and extenſive views over the adjacent country. The other principal ſeats in this vicinity are Cadhay, and Faringdon-houſe. The latter is a very ſpacious manſion, and ſurrounded by luxuriant plantations. Windmill-hill, near this houſe, is ſaid to have been the poſition of a Roman encampment. Polwhele's Hiſtory and Antiquities of Devonſhire, folio. Beauties of England and Wales, vol. iv. by John Britton, F.S.A. and E. W. Brayley.

OTTFRIDE, in *Biography*, a German Benedictine monk, who flouriſhed in the ninth century, was a diſciple of Rabanus, archbiſhop of Mentz, and ſpent the greater part of his life in the monaſtery of Weiſſemburg in Lower Alſace. He became greatly diſtinguiſhed in ſacred and profane literature, and wrote a variety of works in proſe and verſe. He directed his attention to the improvement and purification of the German language, then called the Teutonic, and with this view drew up a grammar, or rather perfected in part that commenced by the emperor Charlemagne. In order that the common people might be inſtructed in the goſpel hiſtory, he wrote a work in Teutonic rhymes, divided into five books, containing the principal circumſtances of the life of Chriſt, taken from the four evangeliſts, and in the order of time. This work was publiſhed by Flacius Illyricus in 1571, but more correctly afterwards by Lambecius, who gives an account of the other works of Ottfride, among which are "Homilies" upon the evangeliſts; and paraphraſes on other parts of the ſacred ſcriptures, &c. Moreri.

OTTINGHAH, in *Geography*, a town of Meckley; 68 miles W. of Munnypour.

OTTMACHAU, a town of Sileſia, in the principality of Neiſſe, on the river Neiſſe; 6 miles W. of Neiſſe. N. lat. 56° 20′. E. long. 17° 2′.

OTTOK, a town of Croatia; 28 miles S.S.W. of Carlſtadt.

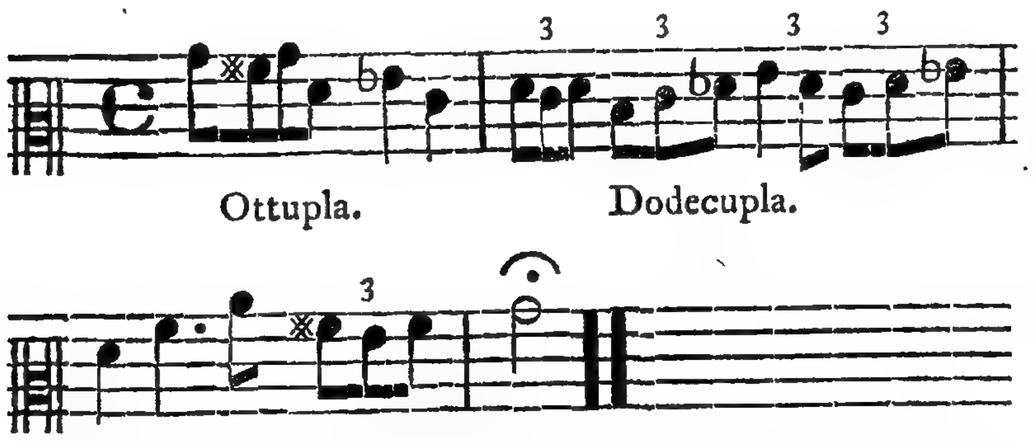
OTTOMAN, or Othoman, an appellation given to the empire of the Turks, or rather to their emperors, from Othomannus, or Oſman, the firſt prince of the family. This Oſman, to diſtinguiſh his followers from others, gave them the name of Oſmanles, from which, by the change of the *s* into *t*, we have made Ottomans; which new name ſoon became formidable to the Greeks of Conſtantinople, from whom Oſman conquered a ſufficient extent of territory to found a powerful kingdom. He ſoon beſtowed on it that title, by aſſuming, in 1300, the dignity of Sultan, which ſignified abſolute ſovereign. The true era of the Ottoman empire may be dated from the conqueſt of Pruſa. The eſtabliſh-

eſtabliſhment of the Ottomans in Europe took place A.D. 1353. See ORCHAN, OTHMAN and TURKEY.

OTTONE, in *Geography*, a town of the Ligurian republic; 21 miles N.E. of Genoa.

OTTSBERG, OTZBERG, or *Utzberg*, a town of Heſſe-Darmſtadt; 26 miles N. of Heidelberg.

OTTUPLA, in the *Italian Muſic*, ſignifies *octuple*, or the meaſure of four times: it is marked with a ſemicircle, C; and ſometimes thus: when it is to be played very quick. In this time, eight quavers are contained in a bar. But it often happens, that ſuddenly, inſtead of two quavers for every time of the bar, three are required; this is called *dodecupla*. It is enough to place a 3 over three quavers, or notes of equal value, to ſhew that the meaſure muſt be changed; and when this 3 is omitted, it ſufficiently demonſtrates the meaſure to be ottupla again: this makes what is called by the Italians *ottupla è dodecupla*, thus:



Ottupla. Dodecupla.

Corelli, in the laſt movement of his tenth ſonata, opera terza, very often uſes an 8 for the dodecupla, to ſhew, that the triple there is changed to common time.

OTTWEILLER, in *Geography*, a town of France, in the department of the Sarre, and chief place of a canton, in the diſtrict of Sarrebruck; 13 miles N. of Sarrebruck. It is ſituated among mountains, and contains a caſtle, a Proteſtant and Roman Catholic church. The place includes 1460, and the canton 7288 inhabitants, in 28 communes.

OTUBUE, a ſmall iſland in the South Pacific ocean, near the coaſt of Bolabola.

OTUGUNGE, a town of Bengal; 24 miles S. of Calcutta.

OTURA, a town of Spain, in the province of Grenada; 5 miles S. of Grenada.

OTUS, in *Ornithology*, the name of the common horn-owl of the ſmaller kind, in many reſpects different from the great horn-owl or eagle-owl. See STRIX.

OTUTUCLA, in *Geography*. See MAOUNA.

OTWAY, THOMAS, in *Biography*, an eminent writer of tragedy, born in 1651, at Trotting in Suſſex, was educated at Wickeham, near Wincheſter, and in 1669 he was entered a commoner of Chriſtchurch, but he left the college without taking his degrees, and without any determination as to the profeſſion which he meant to purſue. He went to London and commenced actor, but not meeting with much ſucceſs he turned his thoughts to writing for the ſtage, and in 1675 produced his firſt tragedy of "Alcibiades." In the ſame year he brought out his "Don Carlos, Prince of Spain," which proved a ſource of great profit, and reſcued the author from a ſtate of extreme indigence. Either his talents as an actor or a writer introduced him to the acquaintance and patronage of men of faſhion and pleaſure, among whom was the earl of Plymouth, a natural ſon of Charles II., who procured for him the commiſſion of cornet in a newly raiſed regiment deſtined for Flanders. This was in the year 1677, and he accompanied his troops to the continent; through habits of diſſipation he returned very ſoon in a ſtate of poverty, reſumed the occupation of writing for the ſtage, and among other pieces he compoſed two tragedies on which his fame is chiefly built, namely "The Orphan," and "Venice Preſerved." Theſe made their appearance in 1680 and 1682. In 1685 he was obliged to conceal himſelf from his creditors, and took refuge in a public-houſe on Tower-hill, where, on the 14th of April, he terminated a miſerable life, at the early age of thirty-four. It was reported, that being nearly famiſhed, he begged a ſhilling of a gentleman, and that he was actually choaked with the bread which he purchaſed and was devouring in the moſt ravenous manner. Dr. Johnſon does not give credit to the ſtory, and Pope was informed that he died of a fever, occaſioned by his exertions in the purſuit of a thief who had robbed one of his friends. "His memory," ſays one of his biographers, "aſſociated with the tender ſcenes that he has written, has been celebrated in various pathetic lamentations for his hard fate, but like many of his fellow-ſufferers, he was too deficient in moral qualities to excite that regard which is the only foundation of ſober ſympathy. Beſides the diſſoluteneſs of manners diſplayed in his life and writings, he was a ſhameleſs flatterer of the great, and ſeems to have had no other public principle than that of a ſervile attachment to authority." The tragedies already mentioned are juſtly accounted ſome of the moſt tender and pathetic that the Engliſh theatre exhibits. No Engliſh poet ever excelled him in touching the paſſions. The heart that does not melt at the diſtreſſes of his Orphan can ſcarcely be human. "Venice Preſerved," without a virtuous character excepting the heroine, at all times excites the deepeſt intereſt, and is at this day very popular, and frequently acted in London, and at the moſt reſpectable country theatres. Although its purpoſe was to paint the horrors and vices of popular inſurrection, he has put into the mouth of his revolutionary hero ſuch forcible declamation againſt the corruptions of government, and ſuch glowing ſentiments of patriotiſm, that it has, occaſionally, even in our times, been thought unfit for public repreſentation. Beſides his dramatic works he compoſed ſome pieces of poetry, which, however, have very little merit. The lateſt edition of Otway's works is that of the preſent year, 1813, in four vols. 8vo. In the year 1719 was printed a piece aſcribed to Otway, but certainly not written by him; it was called "Heroic Friendſhip." That at the time of his death he had made ſome progreſs in a play, is pretty certain from the following advertiſement, printed in L'Eſtrange's Obſervator, Nov. 26, 1686: "Whereas Mr. Thomas Otway, ſome time before his death, made four acts of a play; whoever can give notice in whoſe hands the copy lies, either to Mr. Thomas Betterton, or to Mr. William Smith, at the Theatre Royal, ſhall be rewarded for their pains." Biog. Brit. Johnſon's Lives of the Poets, and Biog. Brit.

OVA, EGGS, in *Natural Hiſtory*. See EGG.

OVA, in the *Human Anatomy*. See FŒTUS and GENERATION.

OVA, among the ancients, a kind of verſes, wherein the verſes were reduced to the form of an egg.

OVA, in *Architecture*, are ornaments in form of eggs, carved on the contour of the ovolo, or quarter round; and ſeparated from each other by anchors or arrows' heads.

The Engliſh uſually call theſe ornaments *eggs and anchors*.

Inſtead of eggs, the ancients ſometimes carved hearts, on which occaſion it was that they introduced arrows, to ſymbolize love.

OUABASH, in *Geography*. See WABASH.

OUA-

OUA-CONG-YN, a town of Thibet; 32 miles S.W. of Hami.

OUADA, or Goa, a town of the Ligurian republic, on the borders of France; 18 miles N.N.W. of Genoa.

OUAGIK, a town of Aſiatic Turkey, in Natolia; 3 miles S. of Iſmid.

OUAIS's Bay, a bay on the N. coaſt of the iſland of cape Breton, in the gulf of St. Lawrence.

OVAL, in *Geometry*, a curve reſembling the contour of an egg, whence its name. The proper oval, or egg-ſhape, is an irregular figure, being narrower at one end than it is at the other; that is, the extreme breadth is not in the middle of its length. In this it differs from the ellipſis, which is the mathematical oval, and is equally broad at both ends.

In the common acceptation of the word the two curves are confounded together, but geometricians conſider the oval as a falſe ellipſe. A figure bounded by circular arcs, ſo meeting as to coincide at the points of meeting with the tangents to the arcs, and as it does not in appearance differ from an ellipſis, is by artificers called an oval.

It may be thus deſcribed, to any given length and breadth. Let the given length A B, (*Plate* II. *fig.* 1. of *Drawing Inſtruments*), and breadth D E, biſect one another, at right angles, at the point C; aſſume the diſtances A F, L B, equal to each other, but leſs than half the breadth C D. Take D G equal to A F; join F G, which divide into two equal parts at H, and from H draw the right line H I perpendicular to F G, meeting the diameter C E in I, and ſet off C K = C I, draw I N and I O, K M and K A. This done, about the centres F and L, with the diſtances A F, L B, deſcribe two ſmall arcs M A N, A B O; which will form the ends of the curve; and about the centres K and I, with the diſtance I N, deſcribe two arcs N D O, M E A, and the oval required will be deſcribed. This curve, though it is called an oval, differs both from the true ellipſis, produced by the oblique ſection of a cone or cylinder, and alſo from the oval or egg-ſhape figure, which is broader at one end than at the other: in fact, it is nothing more than ſegments of different circles combined into one curve, which rather imitates the ellipſis than the oval, its ends being ſimilar.

The egg-ſhaped curve may be deſcribed by means of an inſtrument which has of late been produced with the intention of deſcribing ellipſes, though for this purpoſe it is inapplicable: the principle of its action is explained by *fig.* 2. *Plate* II. In this, ſuppoſe A B an inflexible right line or ruler, the end B connected by a joint to a crank C, which revolves upon a fixed centre D; therefore the end B of the ruler deſcribes the circumference of a circle; the end A of the ruler has a pin projecting from the under ſide of it, which enters a narrow ſtraight groove, its direction being in the line of the centre D: this groove confines the end B to move in a right line tending to the centre of the circle, which the other end, A, deſcribes when the crank is turned round. Now a tracing-point applied at any part of the line A B, will deſcribe a real oval or egg-ſhape, the proportion between its length and breadth being determined by the part of the ruler where the tracer is applied; ſuppoſe it at G, which is half way between the two extremes A, B, then the breadth will be very nearly equal to one-half of the length; at D, which is one-fourth from B, the breadth will be very near three-fourths of the length; and at F, which is one-fourth from the end A, the breadth will only be about one-fourth of the length. It is eaſy to explain this: the length of the oval muſt evidently be equal to the diameter of the circle deſcribed by the crank C; but the breadth will be diminiſhed from this quantity, in the proportion of the parts of the lever A G B, conſidering the end A as its fulcrum, B the point where the action is applied, and G the point where the effect is produced. This reaſoning is general, for if the tracing-point is conſidered as removed to the point B, or within a very ſmall diſtance from it, the oval will have its diameters equal to each other, or the difference between them will be exceedingly ſmall, in which caſe it becomes a circle, or very near it: in like manner, if the point is removed to A, the breadth of the oval will be nothing, producing a ſtraight line. If the ruler is continued beyond the crank to the point H the curve is altered, the breadth being equal to the diameter of the circle, and the length increaſed in proportion to the lever A B H. The reaſon why this curve is larger at one end than the other is, that the point of greateſt elongation of the point B, is when the crank C forms a perpendicular with the ruler A B; this happens at the point *a* of the circle, and produces the greateſt breadth of the curves, as is ſhewn at *b c d*; but theſe points are not equidiſtant, from the two extremes of the length, which will be at *e*, *f*, and *g*; therefore, the line of greateſt breadth, of all curves deſcribed by this means, will not divide the length into equal halves, which is an eſſential condition of the mathematical ellipſis.

The true, or mathematical ellipſis, is a curve which ſo frequently occurs in delineating circular objects in perſpective, that artiſts, as well as geometricians, have been anxious to diſcover a general mode of drawing ſuch curves to any dimenſions and proportions. The principles of ſeveral methods are given in the article Ellipsis; but only one of theſe has been applied in the conſtruction of inſtruments, (ſee Compasses, *Elliptic*,) which is generally denominated by artificers a trammel: this is imperfect, becauſe it will not deſcribe very ſmall or narrow ellipſes, ſuch as are chiefly required in drawing.

Mr. Wilſon Lowry, whoſe engravings accompany this work, has for ſome years made uſe of a very perfect and curious machine for engraving the ellipſes on his plates, many beautiful ſpecimens of which are to be found in our plates of aſtronomical inſtruments, horology, planetary machines, &c.; it operates upon the principle of the elliptic chuck uſed by turners for forming picture frames, and other elliptical work (ſee Rose Engine); but being conſtructed with various adjuſtments for the purpoſe of engraving only, it is not ſo applicable for drawing, as another inſtrument upon a new conſtruction, invented by Mr. John Farey, jun. from whoſe drawings moſt of the above ſubjects are engraved. The Society of Arts have lately preſented the inventor with their gold medal for this inſtrument, which is deſcribed in the 31ſt volume of their Tranſactions. A plan of it is given in our plate at *fig.* 3, and an edge view in *fig.* 4, ſhewing its thickneſs. The general ſize is twice as large as the drawing, but it may be made of any dimenſions at pleaſure. When uſed, it is placed upon the paper or ſurface where the ellipſis is to be deſcribed, and the ſquare frame is held faſt by the left hand, while the moving circles are turned round by the other, to trace the curve by means of a drawing-pen properly ſituated. The moving parts of the inſtrument conſiſt of two circles, A, B, of equal dimenſions, ſo fitted together that they will ſlide one upon the other, by means of the pinion K, uſed to ſeparate their centres any required diſtance within their radii.

The circles have no central bar, but inſtead thereof have two bars *a a*, *a a*, parallel to each other, and at ſome diſtance from the centre, leaving an open ſpace between them, in which the drawing-pen or tracing-point is ſituated: there are two crooked arms *b*, *b*, proceeding from the bars *a*, *a*, to the circular rim, to give it ſufficient ſtrength; and theſe being all the bars acroſs the circles, leave them very open

to ſee the curve, as it is traced beneath by the drawing-pen. The circles are united by ſcrews at *c*, *c*, ſcrewed into the lower circle, and the two bars of the upper circle, being included between them, keep the two together, but at the ſame time admits of their ſliding one upon the other, in the manner of the figure: at *e e* are two other ſcrews tapped into the upper circle, and retaining the lower one in the ſame manner. The centre-pin for the pinion K is fixed on one of the arms of the lower circle, and acts upon a rack, *d*, ſcrewed to the upper circles, ſo that it ſeparates the two, when turned round by the finger and thumb, applied to the milled head upon it.

The circles are fitted together ſo tight by the ſcrews *c c*, and *e e*, that they will not ſeparate from each other, except by the action of the pinion; and may, in the uſe of the inſtrument, be conſidered as firmly united together, though capable of having any degree of excentricity given to them by means of the pinion K.

The circles are turned round in their frame by means of ſix ſmall handles, *f*, fixed in the upper circle, to any oppoſite two of which the thumb and finger of the right hand may be applied. The frame, or fixed part of the inſtrument, conſiſts of four ſtraight rulers D, E, F, G; the latter are ſcrewed down upon the former, and are therefore in a plane above them, as ſhewn by *fig.* 4, plates of braſs being interpoſed between them at the angles, to ſeparate them to a proper diſtance. The lower circle, A, is fitted in between the two lower rulers D, E, and ſlides freely in the direction of their length, but has no ſhake ſideways: in like manner, the upper circle, B, is included between the edges of the rulers F, G, and therefore moves in a right line, in a direction perpendicular to the former. Thus the frame forms two grooves at right angles to each other, in which the circles revolve with an excentric motion, the upper circle ſometimes hanging over the lower rulers, and the lower circle paſſing under the upper rulers, as is ſhewn in the figure. The reſult of this motion is, that a tracer, placed on any part of the circles, when they are rendered excentric, will deſcribe an ellipſis on the ſurface beneath; but the only tracer which is uſed in drawing is ſituated between the bars *a*, *a*: thus, into this ſpace a ſmall carriage, or frame, *g*, is fitted, to ſlide freely from one end of the opening to the other, by means of a rack, *h*, ſcrewed on one ſide of it, and a pinion, L, turning on a centre-pin, fixed into the upper circle: the frame has a braſs ſocket, H, moving on a centre-pin, and having a hole in it for the reception of the leg of a pair of common drawing compaſſes, M, which ſtand as in *fig.* 4: when in uſe, the pen, M, traces the curve upon the paper, but they admit of being turned up on the centre-pin of the ſocket H, and then, for the convenience of ſetting the inſtrument, the circles can be turned about without making any marks. The tranſverſe ſection (*fig.* 5.) ſhews the frame *g g*, and the manner in which it is fitted into the circles, A, B, alſo the ſocket, H, moving on its centre-pin, and the two pair of racks *d*, *h*, and pinions K, L; the former for the purpoſe of ſeparating the circles, and the latter for moving the pen-frame, *g*, along between them: the frame, *g*, is ſo fitted, that it continues at the ſame point with reſpect to the upper circle, when the centres of the two are ſeparated from each other by the pinion K, and may, therefore, be conſidered as immoveable when the lower circle only is moved.

To keep the frame of the inſtrument ſtationary upon the paper whilſt it is uſed, two ſharp pins are fixed in the ruler P, which penetrate the paper, and make it quite faſt, when they are held down by the finger and thumb of the left hand applied upon the heads of nuts N, O; theſe are introduced to unite the ruler P with the ends of the two upper rulers F, G, but the ſcrews of theſe nuts paſſing through grooves in the ruler P, admit the whole inſtrument to be moved on the paper, a ſmall quantity, parallel to itſelf, in the direction of the ruler P; though the friction of the fitting is ſo great, that it will not move unleſs ſome force is applied for that purpoſe: the ſcrews where they paſs through the ends of the rulers F, G, are alſo received in grooves, ſo that by unſcrewing the nuts the whole inſtrument can be moved ſideways, a ſmall quantity nearer or farther from the ruler P; but by ſcrewing theſe nuts faſt, the ſcrews become fixed to F, G, though they ſtill admit of moving in the grooves of the ruler P.

The reader will now comprehend the ſtructure of the inſtrument. The circles are capable of revolving in the frame, ſet with any required degree of excentricity, and the tracing-point or pen can be removed to any required diſtance from the centre of the upper circle. The compaſſes being opened to the extent of two marks made upon one of the bars, G, of the frame, and then being fixed in the inſtrument by puſhing them into their ſocket H, it is ready for uſe. In this ſtate, ſuppoſe the two circles ſet by the pinion, K, exactly concentric with each other, and the pinion, L, turned till the end of the frame, *g*, comes in contact with the rim of the inſtrument, then the point of the tracer will come exactly in the centre of both circles, and the circles being turned round in the frame, the pen will only mark a ſmall point on the paper, which will be the centre of any curve the inſtrument may be made to deſcribe. By turning the pinion, L, the breadth of the ellipſe will be determined, and by the other the difference between its breadth and length is regulated. Suppoſe the pinion, K, turned to render the circles excentric, without moving the other, and the pen therefore remains in the centre of the upper circle; in this caſe the pen will deſcribe a ſtraight line, equal in length to twice the excentricity of the circles: this is evident, becauſe the circumference of the upper circle moving againſt the ſtraight edges F, G, its centre muſt deſcribe a line parallel thereto: this caſe may be conſidered as an ellipſis without breadth, for if the pen is ſet the ſmalleſt quantity out of the centre of the upper circle, it will draw a very narrow ellipſe, and by ſetting it at different diſtances from the centre, any required proportion of ellipſe may be deſcribed.

The conjugate diameter will, in all caſes, be equal to double the diſtance from the point of the pen to the centre of the upper circle, and the difference of the conjugate and tranſverſe diameters will be always equal to twice the excentricity of the two circles

The principle on which this inſtrument operates is the ſame as the trammel employed by carpenters and other artificers for ſtriking ovals, by means of a board with two croſs grooves in it, and a beam or radius-bar, which has two pins to ſlide in the grooves, and a third to draw the curve. To prove this, ſuppoſe P P and Q Q, (*fig.* 6.) to be the two diameters of the intended ellipſes; then if the three points, *d*, *e*, and *f*, are fixed upon an inflexible bar, and the points *d* and *e* conſtantly applied to the two diameters, while a tracing-point, ſituated at *f*, is carried round by the bar; the latter will deſcribe an ellipſis. This is the principle of the trammel; but its defects, as at preſent conſtructed, are well known. 1. It will not draw any ellipſis, which is leſs in either of its dimenſions than the ſize of the board or frame containing the croſs grooves repreſenting the two diameters P P and Q Q; nor can it draw much larger, unleſs the diameters are nearly equal. 2. It is difficult to fix the croſs firmly on the paper, or to bring it to the exact point required for the centre of the ellipſe. And 3. When this is done,

done, the moſt perfect workmanſhip in the grooves and ſliders can ſcarcely enſure that it ſhall move freely without ſhake or improper motions, ſo as to make an accurate and fair curve.

All theſe defects are obviated in the preſent invention, by extending the two points *d* and *e*, to become the large circles A, B, *fig.* 3; then the rulers D, E, F, G, repreſent the ſides of the grooves in which the points move: the point of the pen of the compaſſes now repreſents the point *f* in all its properties of moving along the bar, to enlarge or diminiſh the ellipſe, but with the advantage that it can be actually brought to coincide with one of the points *d* or *e*, when of courſe it will draw a ſtraight line, and if brought to match with both of them, it will deſcribe only a point; therefore this inſtrument will deſcribe any poſſible variety of ellipſe within the limits of its radius, either as to ſize or proportion of its diameters.

In the uſe of this inſtrument, when any ellipſis of given dimenſions is to be drawn, the paper is prepared by drawing the two diameters about four inches long; upon each of theſe ſet off, with the compaſſes, the four points where the intended curve is to interſect the lines. This preparation is not eſſential, but it aſſiſts in ſetting the inſtrument in its true place. The drawing pen of the compaſſes is to be filled with Indian ink from a camel's-hair pencil, and the ſcrew adjuſted, that the pen will draw a proper line; then the leg of the compaſſes being fixed into the braſs ſocket H, ſo that they have no ſhake or looſeneſs in the fitting, the inſtrument is ready for uſe; turn the circles about in the frame, to bring the pen towards the ſide marked G; now place the whole inſtrument in ſuch a poſition, that the centre of the four rulers coincides with the centre of the intended ellipſis. This may be eſtimated, or, by previouſly producing the two diameters, the frame may be ſet very nearly, taking care to place the upper rulers F, G, parallel to the greateſt diameter: here fix the inſtrument by preſſing the two pins or points of the ruler P into the paper, and hold it faſt by placing the thumb and fore-finger of the left-hand upon the nuts N, O, leaving the other hand at liberty to turn the circles about, by applying the finger and thumb to any oppoſite two of the ſmall handles *f*. Now by turning the pinion L, remove the drawing pen to the mark made for the extent of the ſhorteſt diameter of the ellipſis; then turn the circles one-half round by the handles, and examine if the point of the pen comes exactly to the oppoſite mark for the end of the ſhorteſt diameter; if it does not, adjuſt the error, one-half by moving the pen, by turning the pinion L, and the other half, by moving the whole frame on the paper. The ſcrews of the nuts N, O, will admit this motion, being fitted into grooves in the ruler P, (which ſhould not be diſturbed,) but the nuts ſhould not be ſcrewed ſo tight as to prevent the motion; then, by returning the circles back again its accuracy will be aſcertained; for if it meets the former mark, it proves that the circles are in the right centre, and the compaſſes are ſet to the proper diameter for the conjugate axis: now turn the pen towards the length of the ellipſis, and without altering the compaſſes or pinion L, ſlide the circles one upon another by the pinion K, till the point of the pen arrives at the mark made for the length of the ellipſis: turn the circles half round to the oppoſite end, and if they match the mark made there the adjuſtment is correct; if not, one-half the error muſt be corrected, by moving the circles by their pinion K, and the other by moving the whole frame ſideways on the paper. To do this, the nuts N, O, muſt be made ſlack, and then the frame will be at liberty to move; but the ruler P muſt never be removed after the firſt fixing, and the ſide of the frame will, of courſe, be at a greater or leſs diſtance from it. The adjuſtments being made in this manner, the pen may be ſuffered to reſt upon the paper and trace round the curve. The precautions of turning the circles to the oppoſite ſides will be unneceſſary, except where great accuracy is required. In turning the circles about, a habit will be acquired of preſſing with equal force on the two oppoſite ſides of the circles, and then they will turn round eaſily.

It will ſave much trouble, in adjuſting the place of the inſtrument upon the paper, if the compaſſes, before being put into the ſocket H, are opened to the extent of the two marks upon the bar G; then the compaſſes are put into their ſocket, and if this is removed by turning the pinion, L, till the end, *g*, comes in contact with the rim of the circle, the point of the pen will come exactly into the centre of the ellipſis which it is intended to deſcribe; if, therefore, the centre of the ellipſis is marked upon the paper, and the point of the pen (when opened to the above extent, and the ſocket kept back as far as it will go) being brought by moving the whole frame on the paper to this mark, the inſtrument is adjuſted at once as to its poſition on the paper, and the other adjuſtments for the dimenſions of the ellipſis required to be drawn may be made as before directed.

After having drawn an ellipſis, if it is required to draw another parallel to it, to ſhew the thickneſs of a circular plate, for inſtance, ſet the pen oppoſite G, and by the ſcrews of the nuts N, O, as before mentioned, being fitted in grooves, the frame and the circles may be moved with the longer axis parallel to itſelf, ſo as to deſcribe another ellipſis parallel to the former. By this means all kinds of circular mouldings, wheels, &c. may be drawn with the greateſt accuracy and expedition; but the various uſes to which it is applicable, are beſt ſhewn by the numerous perſpective drawings in our plates, wherein Mr. Farey employs it for all the ellipſes.

Oval *Column*. See Column.

The ancients have been repreſented as authoriſing this deformed figure for the plan of a column: but this is a miſtake, probably occaſioned by the diſcovery of fragments, where flanked columns have been ſet back to back againſt a ſcreen or wall of nearly the ſame width with the diameters of the columns: theſe remains, defaced by time, might ſuggeſt, to a ſuperficial enquirer, that the column originally had an oval baſe.

Oval *Crown*. See Crown.

Oval *Ellipſis*, an oblong curvilinear figure with two unequal diameters; or a figure encloſed with a ſingle curve line, imperfectly round, its length being greater than its breadth, like an egg; whence its name. See Oval.

The method of deſcribing an oval, chiefly uſed among workmen, is by a cord or ſtring, as F *f* M (*Plate* IX. *Conics*, *fig.* 18.) whoſe length is equal to the greater diameter A B of the oval, and which is faſtened, by its extremes, to two points or nails, F, *f*, planted in its longer diameter; by which means the oval is made ſo much the longer, as the two points or nails are farther apart.

Oval *Foramen*, *Ruptures of*, in *Surgery*. See Hernia.

Oval *Leaf*, in *Botany*. See Leaf.

OUALALDE, in *Geography*, a town of Africa, in the country of the Foulahs, on the ſide of the Senegal. N. lat. 18° 45′. W. long. 13° 8′.

OVALE Foramen, in *Anatomy*. See Heart.

OVALLE, Alonzo de, in *Biography*, a Jeſuit, was

born at Santiago in Chili, and became procurador-general of the order in that province. He went to Rome to obtain a ſupply of miſſionaries, and there he publiſhed a work entitled "Hiſtorica Relacion del Reyno de Chile, y de las miſſiones y miniſterios que exercita en el la Compania de Jeſus," 1646. "This," ſays Mr. Southey, "is a book of great value, though it is meanly printed, and the engravings are execrably bad. At the end of the copy now before me are ſome views of the Jeſuit ſettlement in Chili, and of the ſix principal forts, which were publiſhed ſeparately to be purchaſed at pleaſure. They are, without exception, the very worſt I have ever ſeen." An abridgment of Ovalle's work is in Churchill's collection. Gen. Biog.

OUAN, in *Geography*, a town of Corea; 53 miles W.S.W. of Koang.—Alſo, a town of China, in the iſland of Hai-nan; 75 miles S. of Kiong-tcheou.

OUANAMINTHE, a town of Hiſpaniola; 15 miles S.E. of Fort Dauphin.

OUANDERON, in *Zoology*. See SIMIA *Silenus*.

OVANDO, in *Geography*, a province or duchy of the kingdom of Congo in Africa, ſituated between Congo and Angola, now in the poſſeſſion of the Portugueſe, but formerly ſubject, or tributary, to the kings of Congo. Its capital, called St. Michael, is ſeated on the river Danda, but is a place of no great note.

OUANGARUM, a river of Canada, which runs into the St. Lawrence, N. lat. 44° 37'. W. long. 75° 45'.

OUANG-KOA, a town of Corea; 28 miles E.S.E. of Koang-tcheou.

OUANLIN-HOTUN, a town of Chineſe Tartary; 588 miles N.E. of Peking.

OUANNE, a town of France, in the department of the Yonne; 9 miles S.W. of Auxerre.

OUAQUAPHENOGAW, or EKANFANOKA, or *Okerfonoke*, a lake or rather marſh of America, between Flint and Oakmulgee rivers, in Georgia, about 300 miles in circumference. In wet ſeaſons it appears like an inland ſea, and has ſeveral large iſlands of rich land, one of which is repreſented by the Creek Indians as the moſt bliſsful ſpot on earth. They ſay it is inhabited by a peculiar race of Indians, whoſe women are incomparably beautiful. They alſo relate many other wonderful ſtories concerning this iſland, which it is needleſs to recite.

OUANTOU, in *Ornithology*. See PICUS, *lineatus*.

OVAR, in *Geography*, a conſiderable town or villa of Portugal, in the province of Beira; 15 miles S. of Oporto. It contains 1300 houſes, of which many are large and handſome. An arm of the Vouga, which is properly a lake, and which is narrow for three leagues and then becomes much broader during a league, then forming a true lake, and at length ends in a narrow channel a league long, ceaſes cloſe to Ovar.

OUARA, a town of Hindooſtan, in Bahar; 65 miles S.S.W. of Patna.

OUARANGUE, a ſmall iſland in the Atlantic, near the coaſt of Africa. N. lat. 11° 32'.

OUARDAN. See VARDAN.

OUARINE, in *Zoology*. See SIMIA *Beelzebub*.

OVARY, in *Anatomy*. See GENERATION.

OVARY, *Dropſy of*. See DROPSY.

OVARY *of Birds*. See *Anatomy of* BIRDS.

OVARY *of Fiſh*. See FISH.

OUASIOTO MOUNTAINS, in *Geography*, mountains of America, ſituated N.W. of the Laurel mountains in North Carolina and Virginia; 50 or 60 miles wide at the Gap, and 450 in length, N.E. and S.W. They abound in coal, lime, and free-ſtone. Their ſummits are for the moſt part covered with good ſoil and a variety of timber, and the intervening lands are well watered.

OVATED LEAF, among *Botaniſts*. See LEAF.

OVATION, OVATIO, in the *Roman Hiſtory*, a leſſer triumph allowed to commanders for victories won without the effuſion of much blood; or for the defeating of rebels, ſlaves, pirates, or other unworthy enemies of the republic.

Their entry was on foot; ſometimes on horſeback; but never in a chariot: and they wore crowns of myrtle, called *ovales*; having all the ſenate attending in their retinue.

The denomination ovatio, according to Servius, and Plutarch, in his life of Marcellus, is derived from *ovis*, *ſheep*; becauſe the conqueror ſacrificed a ſheep on this occaſion to Jupiter; whereas, in the greater triumph, they ſacrificed a bull.

Others derive it from the ſound or din of the acclamations and ſhouts of joy, made by the people, in honour of the ſolemnity; the people and ſoldiery, on this occaſion, redoubling the letter O, as in the great triumph they did the words, *Io triumphe*.

The ovation was firſt introduced in the year of Rome 325, in honour of the conſul Poſthumius Tubertus, after his defeating the Sabines.

OUBINSKOI MOUNTAINS, in *Geography*, otherwiſe called *Vobrofskoi*, mountains of Ruſſia, which form, at the ſources of the Ouba and Ulba, a conſiderable ridge, towering in lofty ſummits to high ſnow-mountains, ſending out its branches on both ſides of thoſe rivers, eſpecially between them, and at its foot bordered by the Irtiſch. The greateſt height riſes near Bobrofskaia with porphyry, which in the north and ſouth is frequently changed for granite, whoſe ſummits, ſometimes with gentle, and then with bold aſcents, ſurround the moſt delightful vales, abounding in odoriferous herbs of various kinds. In the region about the fortreſs Ouſtkameneyorſk, the granite is under-run by ſchiſtoſe earth, in ancient times explored by the Tſhudi, who took pleaſure in mining. Higher up the Irtiſch, as far as the Buktorma, mountains of ſchiſtus frequently appear, in which copper-ore is dug, and which is, here and there, under-run by porphyry and granite, but in many places covered with chalk. The mountains in which are the ſources of the Ouba conſiſt of granite, porphyry, marlwake, petroſilex, and quartz. Towards the eaſt the Oubinſkoi mountains rear their lofty ſummits, which, meaſured with the line, were found to be 5691 Engliſh feet above the water of the river Ouba, which devolves its pleaſant ſtreams beneath their monſtrous cliffs. In theſe mountains have been lately found the Filipofskoi mines, on the Ulba, which promiſe great ſucceſs, together with other mines. Tooke's Ruſſ. vol. i.

OUCARRA, a town of Hindooſtan, in the Myſore; 5 miles S. of Sattimungulum.

OUCENTA, a town of Naples, in Lavora; 12 miles E. of Capua.

OUCH, in our *Old Writers*, a collar of gold, or ſuch like ornament, worn by women about their necks. Stat. 24 Hen. VIII. cap. 13.

OUCHE, in *Geography*, a town of Switzerland, on the lake of Geneva; which is the port of Lauſanne.

OUCHTERMUCHTY, a borough town, ſituated in the county of Fife, Scotland, was conſtituted a royal borough by king James IV., and the charter was ſubſequently confirmed by James VI. This place ſtill continues to enjoy all its original privileges, except the right of ſending members to parliament, or to the convention of royal boroughs. The government

government is veſted in three baillies and fifteen counſellors, who are elected annually; and there is a weekly market for proviſions. A very conſiderable manufacture of brown linens and Sileſias is carried on here, as are likewiſe ſome tan-works. The pariſh extends about two miles in length and one and a half in breadth, and diſplays much variety of ſurface. In the immediate vicinity of the town the ſoil is gravelly, but at a greater diſtance is fertile. Free-ſtone and marle are abundant. According to the parliamentary returns of 1811 the whole pariſh compriſes 525 houſes, and a popuiation of 2403 perſons. Beauties of Scotland, vol. iv.

OUDAL, a town of Norway, in the province of Aggerhuus; 40 miles N.E. of Chriſtiania.

OUDAPOUR, a town of Bengal; 15 miles E. of Comillah.

OUDATUM-OUDOUC, a town of Chineſe Tartary. N. lat. 45° 9′. E. long. 121° 28′.

OUDE, a province or ſoubah of Hindooſtan, the dominions of which lie on both ſides of the Ganges, occupying (with the exception of Fezoola Cawn's diſtrict of Rampour) all the flat country between that river and the northern mountains towards Thibet, as well as the principal part of the fertile tract lying between the Ganges and Jumnah, known by the name of Dooab, to within 40 miles of the city of Delhi. On the E. and S.E. it is bounded by Bahar, on the S. by Allahabad, ceded by treaty to the Engliſh in 1793, and on the W. by Agra. According to the ſtatement of Major Rennell, in the Introduction to his Memoir, the dimenſions of Oude, and its dependencies, may be reckoned 360 Britiſh miles in length from E. to W., and in breadth from 150 to 180; and their area is about one-third part of that of the Bengal provinces; being to each other in the proportion of 53 to 162. Generally ſpeaking, the whole territory is one continued plain; and is a continuation of that extenſive level valley through which the Ganges, and its branches, take their courſe. It is, moreover, the central part of the ancient kingdom or empire of the "Praſii." Lucknow, ſituated on the river Goomty, and about 650 miles from Calcutta, is its preſent capital; having ſuperſeded Fyzabad, a city on the Gogra, near the ancient city of Aiudh, which ſeems to have given name to the province. The nabob of Oude is in alliance with the Britiſh power: and a brigade of the Bengal army is conſtantly ſtationed on his weſtern frontier; thus anſwering the purpoſes of covering Oude as well as Bengal, and of keeping the weſtern ſtates in awe. It is advanced about 100 miles beyond Lucknow. The whole expence of it is paid by the nabob of Oude, by a ſtipulated ſum, under the name of a ſubſidy, amounting annually to 420,000*l.*, provided the Sicca rupee be valued at 2*s.* 1¼*d.* The late nabob of Oude, Sujah Dowlah, poſſeſſed, at the time when he firſt became an ally of the Eaſt India company, the whole ſoubah of Oude, and the greateſt part of Allahabad; to which, in 1774, were added the eaſtern parts of Delhi and Agra, till that time poſſeſſed by a tribe of Afghan Rohillas, and by the Jats. The Zemindary of Benares, which includes alſo the circars of Gazypour and Chunar, conſtituted a part of the dominions of Oude until the year 1775, when its tribute or quit-rent of 24 lacks (ſince increaſed to 40) was transferred to the Engliſh. This Zemindary, which was lately in the hands of Chut Sing, occupies the principal part of the ſpace between Bahar and Oude, ſo that only a ſmall part of the territory of the latter touches Bahar on the N.W. The revenues of Oude under Aurungzebe amounted to 80½ lacks of rupees; but they have more lately been reckoned in the groſs amount at about 2½ millions ſterling; of which the new acquiſitions of Rohilcund, Corah, and other parts of the Dooab, are more than one million. The military eſtabliſhment, including the troops employed in the collection of the revenues, is from 50 to 60,000 men; but few of them deſerve the name of regular troops.

The province of Oude is watered not only by the Ganges, but by the Jumnah, Agra, Goomty, and ſeveral ſmaller ſtreams; theſe flow through moſt of the principal towns, and are navigable for boats in all ſeaſons of the year. They preſent ſtrong barriers againſt the neighbouring powers. Oude has ſeven circars, *viz.* Bahraitch, Canoge, Goorackpour, Kairabad, Lucknow, Manickpour, and Oude proper.

Oude, a circar of Hindooſtan, in the ſoubah of Oude, bounded on the N. by Bahraitch, on the E. by Goorackpour, on the S. by Jionpour and Manickpour, and on the W. by Lucknow; about 45 miles long and 16 broad. Its capital is Fyzabad.

OUDENARDE, a town of France, in the department of the Scheldt, and principal place of a diſtrict, ſituated on the Scheldt; ſuppoſed by ſome to have been built by the Goths in the year 411. It lies in a valley, on the ſide of a mountain called "Kerſelaerberg," which defends the city. It has two pariſh churches, five gates, and many good buildings. The town has two juriſdictions; one of the magiſtracy, compoſed of a grand bailiff, a burgomaſter, and nine echevins; the other in the hands of the lords: theſe juriſdictions are ſeparated by the Scheldt. This town was ſo well fortified by Francis de la Noüe, a French Calviniſt, that it was called "Little Rochelle." Oudenarde ſurrendered to the French on the 3d of July, 1794; 12 miles S. of Ghent.

OUDENBORG, a town of France, in the department of the Lys; ſix miles S.E. of Oſtend.

OUDENBOSCH, a town of Brabant; 10 miles W. of Breda.

OUDERKERCK, a town of Holland; ſix miles S. of Amſterdam.

OUDEWATER, a town of Holland, ſeated on the Little Iſſel, to which Henry de Vianen, biſhop of Utrecht, gave the privileges of a city, in the year 1254. In 1575 it was taken by aſſault, pillaged and burnt by the Spaniards, who murdered, among many others, the mother, ſiſters, and brothers, of the celebrated James Arminius, who was born here in the year 1560; 20 miles S. of Amſterdam.

OUDGAH, a town of Bengal; 54 miles S.E. of Doeſa.

OUDGASTEL, a town of Brabant; 12 miles W. of Breda.

OUDIA, Cape, or *Capoudia*, a cape on the E. coaſt of Tunis. N. lat. 30° 45′. E. long. 11° 2′.

OUDIGHIR, a town of Hindooſtan, in Dowlatabad; five miles N.W. of Beder.

OUDIN, Casimir, in *Biography*, a learned French monk, in the ſeventeenth and eighteenth centuries, who afterwards embraced the Proteſtant religion, was born at Meſières, on the Meuſe, in the year 1638. He diſcovered an early inclination for learning, and after having gone through his courſe of rhetoric, at the age of eighteen he entered among the monks of the Premontrè order at the abbey of St. Paul at Verdun. Here he applied himſelf to the ſtudies of the place, but in his future life he attached himſelf chiefly to eccleſiaſtical hiſtory, and made it a principal purſuit. In 1675 he entered holy orders, and was appointed incumbent of Epinay, in the dioceſe of Rouen. In 1677 he reſigned this benefice, and was placed by his ſuperiors in the abbey of Bucilly in Champagne. In the following year he was ſent on a viſit to all the abbeys and churches belonging

belonging to his order, for the purpoſe of ſelecting from their archives ſuch documents as might aſſiſt him in his enquiries into eccleſiaſtical hiſtory. He firſt viſited the monaſteries in the Netherlands, whence he brought back with him a rich ſupply of materials, and in 1682 he made the ſame reſearches in the religious houſes of Lorraine, Burgundy, and Alſace. In 1683 he was ſent to Paris, where he formed connections with ſeveral eminent characters in the republic of letters, and in 1688 he publiſhed a work, by which he acquired great credit, entitled "Supplementum de Scriptoribus vel Scriptis Eccleſiaſticis à Bellarmino omiſſis, ad annum 1460, vel ad artem typographicam inventum." In 1690 he found reaſon to change his religious ſentiments and profeſſion, withdrew from France and went to Leyden, where he renounced the popiſh creed, and made a public profeſſion of the Proteſtant religion. Soon after this he was appointed ſub-librarian of the univerſity of Leyden, a poſt which he retained till his death in 1717. He was author of many other works, as "Acta Beati Lucæ Abbatis Cuſſiacenſis:" "Veterum aliquot Galliæ et Belgii Scriptorum opuſcula ſacra numquam edita;" "Epiſtola de ratione Studiorum ſuorum;" and ſeveral others: but his principal work was entitled "Commentarius de Scriptoribus Eccleſiæ Antiquis, illorumque Scriptis; adhuc extantibus in celebrioribus Europæ Bibliothecis, a Bellarmino, Poſſevino, Phil. Labbeo, Guil Caveo, El du Pin, &c." in three volumes, folio.

Oudin, Francis, a learned French Jeſuit, was born at Vignorix, in Champagne, in the year 1673. He was ſent very young to commence his ſtudies at Langres, where he made a conſiderable progreſs in his acquaintance with the ſciences and the belles lettres. He reſolved to embrace the eccleſiaſtical profeſſion, and commenced his noviciate among the Jeſuits, at Nancy, in 1691. He afterwards became profeſſor of rhetoric at the college of Dijon, and then undertook the profeſſorſhip of theology, the duties of which he performed with high reputation during fifteen years. He died at Dijon in 1752, at the age of ſeventy-nine. He was a good linguiſt; was profoundly ſkilled in the knowledge of ſacred and profane antiquities, and in the ſcience of medals. He was alſo diſtinguiſhed by his taſte in polite literature, and had a wonderful facility in compoſing Latin verſes. He was author of many "Poems," "Odes," "Elegies," "Hymns," &c. of which the greater part was inſerted in a collection entitled "Poemata didaſcalia," in three volumes, 12mo. His proſe works were numerous, conſiſting of "Diſſertations," "Eulogies," "Lives," &c.: and alſo of Commentaries on many parts of the ſcriptures. He was, towards the cloſe of life, employed by his ſuperiors on a continuation of the "Bibliotheca Scriptorum Societatis Jeſu," which was begun by father Ribadeneira. Moreri.

OUDINET, March Antony, a medaliſt, was born at Rheims in 1643; he was profeſſor of the law at his native place, and afterwards obtained the office of keeper of the royal cabinet of medals. He was alſo a member of the Academy of Inſcriptions, and died in 1712. He wrote three memoirs on medals.

OUDIPOUR, Meywar, or *Midwar*, in *Geography*, a province of Hindooſtan, belonging to the Rajpoots, about 100 miles long, and about as much in breadth, ſituated on the E. of the river Puddah. In former times, it is probable that the whole Rajpootana conſtituted one kingdom or empire under the rajah or prince of Oudipour, who has always been conſidered as the head of the Rajpoot ſtates. In modern times this rajah ſeems to have been regarded much like the general of the Amphictyons in Greece. Oudipour is very mountainous, with a ſandy ſoil in the vallies. Its revenue in the year 1779 was eſtimated at 10 lacks of rupees *per annum*.—Alſo, the capital of the circar to which it gives name, in the country of Agimere; 120 miles S.S.W. of Agimere. N. lat. 24° 42′. E. long. 74° 42′.

OUDOBO, a country of Africa, ſubject to Benin.

OUE, a mountain of Perſia, in Khoraſan; eight miles E. of Kaïn.

OUEI-LO, a town of Thibet; 295 miles S.W. of Hami.

OUEI-NING, a city of China, of the firſt rank, in Koei-tcheou. N. lat. 26 45. E. long. 103° 50′.

OUEI-YUEN, a town of Thibet; 275 miles E.S.E. of Hami.

Ouei-yuen *Hotun*, a town of Corea; 450 miles E.N.E. of Peking.

OUE-KIUM, a town of China, of the firſt rank, in Honan, on the river Ki; 297 miles S.S.W. of Peking.

OVELGUNN, a town of the duchy of Holſtein; nine miles E.S.E. of Eutyn.

OVELGUNNE, or Ovelgoenne, a town of Germany, and chief place of a ſmall territory, which, in 1653, was annexed to the comté of Oldenburg; 16 miles N.E. of Oldenburg.

OVELTY. See Owelty.

OVEN, or *Aſſaying* Oven, in *Metallurgy*, is the particular ſort of furnace uſed by the aſſayers in their operations on metals. See *Aſſaying* Furnace.

OUEN-TCHEOU, in *Geography*, a city of China, of the firſt rank, in Tche-kian, on a river with a good harbour, not far from the ſea; 765 miles S.E. of Peking. N. lat. 28 1′. E long. 120 29′.

OUEN-TCHUEN, a town of Corea; 85 miles N.E. of King-ki-tao.

OUEN-Y, a town of Corea; 20 miles S.S.W. of Ou-tcheou.

OUEN-YEN, a town of Corea; 33 miles S.S.W. of Ou-tcheou.

OUEPAS, a town of Mexico, on the coaſt of Coſta Rica, S. of Carthago.

OVERA. See Awerri.

OVERACKEN, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 63 50′. E. long. 20° 29′.

OVERALL, John, in *Biography*, a learned prelate of the church of England, was born about the year 1559. From the grammar-ſchool he was ſent to St. John's college, in the univerſity of Cambridge, of which ſociety he was elected a ſcholar; after this he removed to Trinity college, where he was choſen a fellow. In the year 1596 he was nominated Regius profeſſor of divinity, and took the degree of doctor in that faculty. About the ſame time he was elected maſter of Catherine-hall, and ſoon after was promoted to the deanery of St. Paul's, London. On the acceſſion of James I. he was choſen prolocutor of the lower houſe of convocation, and in 1612 he was appointed one of the firſt governors of the Charter-houſe, then juſt founded. In 1614 he was nominated to the ſee of Litchfield and Coventry, from which, in four years, he was tranſlated to that of Norwich, where he died in 1619, at the age of about ſixty. He particularly excelled in ſcholaſtic theology; and declared himſelf without heſitation in favour of Arminianiſm. He is chiefly known as the author of a work entitled "The Convocation-Book," to which Dr. (afterwards biſhop) Sherlock, attributed his converſion from nonjuring principles. See Biog. Brit. notes to the article Sherlock.

OVER-BLOW, in *Sea Language*. They ſay it overblows when the wind blows ſo very hard that the ſhip can bear no top-ſails.

OVER-BOARD denotes the ſtate of being thrown out of a ſhip or boat into the water on which ſhe ſwims; alſo the act of falling from ſuch a veſſel into the ſea, &c. as the ſhip ſprung a-leak, and obliged us to throw the guns over-board; or, a heavy ſea broke over the deck, and carried two of our men over-board.

OVERBURY, *Sir* THOMAS, in *Biography*, an Engliſh gentleman, was deſcended from an ancient family at Aſhton-under-Edge, in Glouceſterſhire. He was born in 1581, at the houſe of a maternal relation in Warwickſhire, and after having laid the foundation of his grammar learning in that country, he was entered as a gentleman commoner of Queen's college, Oxford. From this place he removed to the Middle Temple for the ſtudy of the law, to which profeſſion his father belonged, but not having a taſte for legal purſuits he endeavoured to puſh his fortune at court. About the year 1604 he contracted an intimacy with Robert Carr, the favourite of king James (ſee the article JAMES I.), who was afterwards created earl of Somerſet, and by whoſe means Mr. Overbury was knighted, and his father raiſed to the honour of being a Welſh judge. This was in the year 1608, and in the following year ſir Thomas made a tour on the continent, and on his return publiſhed "Obſervations on what he had ſeen." It was not likely that his principles ſhould be pure while connected with a licentious court; and accordingly it appears that he aſſiſted his friend and patron Carr, then lord Rocheſter, in his amorous correſpondence with the counteſs of Eſſex, but after her divorce, he as earneſtly oppoſed the marriage of the two adulterers, for which he incurred the hatred of them both. An attempt was now made to remove ſir Thomas to a diſtance from the court by appointing him to a foreign embaſſy, but he refuſed compliance; and upon the ground of his refuſal to undertake the king's ſervice he was committed to the Tower in April 1612, and all acceſs of his friends was denied him. Carr not only prevented the effect of every application for Overbury's releaſe, but is ſaid, by his own warrant, to have continued the ſtrictneſs of his impriſonment, contrary to the uſual practice in ſuch caſes. By his procurement, and that of his counteſs, poiſon was adminiſtered to him while a priſoner, and he died in extreme torture on the 15th of September 1613. Two years afterwards the circumſtance of Overbury's death was diſcovered, the accomplices in the horrid murder were tried, and the lieutenant of the Tower, with ſeveral others, were condemned and executed. Carr and the lady, at that time the earl and counteſs of Somerſet, were alſo convicted and condemned, but were pardoned. Sir Thomas, though by no means a blameleſs character, was lamented as a victim to the paſſions of a moſt abandoned pair. He was author of ſeveral pieces in proſe and verſe. The poem entitled "The Wife," deſcribing the character of a woman qualified to render the marriage ſtate happy, was extremely popular. The tenth edition of his works was publiſhed in 8vo. in 1753. Biog. Britannica. In this work there is a long and very detailed account of the methods uſed to deſtroy ſir Thomas Overbury.

OVER-CAST-STAFF, is a ſcale or meaſure, uſed by ſhipwrights, to determine the difference between the curves of thoſe timbers which are placed near the greateſt breadth, and thoſe which are ſituated near the extremities of the keel, where the floor riſes and grows narrower.

OVER-DONE, in the *Manege*, in French, *outré*. A horſe is ſaid to be over-done, or *outré*, when his wind and ſtrength are broke and exhauſted with fatigue.

OVER-FALL, or TUMBLING-BAY, in *Geography*, is a part of the ſide of a canal, or reſervoir, over which the water runs away, or eſcapes, when it is too high.—Alſo, the upper gates or ſluices of opening weirs are called *over-falls*.

OVERFLAKEE, OVER-FLACQUEE, or *Zuidvorn*, an iſland of Holland, on the Meuſe, about 13 miles long from E. to W., and four in its greateſt breadth. The firſt name it derived from a ſand-bank, called "Flacque" or "Flakee," which lies in the ſtream N. of the iſland, and the laſt from its ſituation with reſpect to the iſle of Voorn, from which it is about two miles diſtant to the ſouth. N. lat. 51° 43'. E. long. 4° 24'.

OVERFLAX, a town of Sweden, in the government of Waſa; ſix miles N. of Waſa.

OVER-FLOWING, or INUNDATION *of Land*. See IRRIGATION, *Flooding of* LAND, and WATERING *of Land*.

OVER-GROWN, in *Sea Language*. When the waves of the ſea grow high, the ſailors call it *rough ſea*; but when the ſurges and billows grow vaſtly high, then it is an *over-grown ſea*.

OVER-HANGING, in *Ship Building*, projecting over; as the ſtern is ſaid to overhang when it rakes much.

OVER-HAUL, in *Sea Language*. A rope is ſaid to be over-hauled, when drawn too ſtiff, or hauled the contrary way.

OVER-HAUL *the Runner*. See RUNNER.

OVER-HAUL *the Sheet*. See SHEET.

OVER-HAULING denotes the act of opening and extending the ſeveral parts of a tackle, or other aſſemblages of ropes, communicating with blocks or dead-eyes. It is uſed to remove thoſe blocks to a ſufficient diſtance from each other, that they may be again placed in a ſtate of action, ſo as to produce the effect required.

OVER-HAULING is alſo vulgarly expreſſed of an examination or inſpection into the condition of a perſon or thing.

OVERISSEL, in *Geography*, a department of Holland, which was one of the ſeven united Dutch ſtates, bounded on the N. by Groningen and Freiſland, on the E. by the biſhopric of Munſter and county of Bentheim, on the S. by Guelderland, and on the W. by the Zuyder See. The ſoil, except towards the W., where are ſome corn-lands and paſtures, is generally marſhy and productive of heath; the land is moſtly common without incloſure, and without aſcertained property. Near the river, however, are ſome incloſed meadows, which yield good hay. The whole country is flat and low, excepting merely a ridge which runs through it from N. to S. It is divided into three diſtricts, *viz.* Salland, Twent, and Vollenhoven; to which may be added Drent dependent upon it. The principal towns are Deventer, Campen, Zwol, and Vollenhoven, with Aſſen and Coverden in Drent. The chief rivers are the Iſſel and Vecht.

OVER-LAND FARM, in *Agriculture*, a provincial word uſed to ſignify a parcel of land without a houſe to it.

OVER-LAUNCH, in *Ship Building*, to run the butt of one plank to a certain diſtance beyond the next butt above or beneath it, in order to make ſtronger work.

OVER-LAYING *of Children*, may be prevented by a machine called *arcuccio*.

OVER-MASTED, in *Sea Language*, denotes the ſtate of a ſhip, whoſe maſts are too high, or too heavy for the weight of her hull to counterbalance.

OVER-RAKE. When a ſhip, riding at anchor, ſo over-beats herſelf into a head-ſea, that ſhe is waſhed by the waves breaking in upon her; they ſay, the waves over-rake her.

OVER-REACH, in the *Manege*, is when a horſe ſtrikes his hind-feet againſt his fore. The

The word is alſo uſed for a ſtrain, or painful ſwelling, of the maſter-ſinew of a horſe; occaſioned by ſuch over-reach.

OVER-RIDE, the ſame with over-done.

OVER-RULING *an Objection*, in *Law*, is the rejecting or ſetting it aſide by the court.

OVER-RUNNING, among *Printers*. See PRINTING, and CORRECTION.

OVERSAMESSA, an ancient fine or penalty, impoſed before the ſtatute of hue and cry, on ſuch perſons, as, hearing of a robbery or murder, did not purſue the malefactor.

OVERSEERS *of the Poor*, are public officers, who muſt be ſubſtantial houſeholders, (under which relative term day-labourers may be comprehended, if there be no other perſon to ſerve, and they muſt be generally reſident in the pariſh,) created by the ſtat. 43 Eliz. cap. 2. and nominated yearly in Eaſter week, or within one month after Eaſter (though a ſubſequent nomination will be valid) under the hand and ſeal of two or more juſtices of the peace in the ſame county, and dwelling in or near the pariſh whereof one to be of the quorum, who muſt meet together for this purpoſe; to provide for the poor of every pariſh; and are ſometimes two, or three, or four, according to the largeneſs of the pariſh: but not more than four nor leſs than two can be appointed. By 17 Geo. II. c. 38. in every townſhip or place where are no churchwardens, the overſeers alone may act in all reſpects as churchwardens and overſeers may do in other places by virtue of this or any former act; and if any overſeer ſhall die, or remove, or become inſolvent, before the expiration of his office, two juſtices (on oath thereof made) may appoint another in his ſtead; and if in any place there ſhall be no ſuch nomination of overſeers, as is before appointed, every juſtice of the diviſion ſhall forfeit 5*l.* to the poor of ſuch place, to be levied by the churchwardens and overſeers, or one of them, by diſtreſs by warrant from the ſeſſions. (43 Eliz. c. 2.) This forfeiture ſuppoſes that the juſtices are obliged to divide, for in that caſe the appointment was to be by the juſtices in or near the diviſion, and not otherwiſe; but now the juſtices at large are all equally concerned; and therefore it ſeems, that this penalty cannot be levied on any particular juſtice. But if, in any place, no overſeer ſhall be appointed, a mandamus will go to the juſtices at large, to compel them to appoint. Pariſhioners, as well as overſeers appointed, may appeal to the ſeſſions againſt the appointment. (17 Geo. II.) Overſeers refuſing to take the office may be indicted for it; nor will the court quaſh an indictment againſt an overſeer. The overſeers thus appointed, and taking upon them the office, ſhall, within fourteen days, receive the books of aſſeſſment and accounts from their predeceſſors, and what money and materials ſhall be in their hands, and reimburſe them their arrears. 17 G. II. cap. 28.

Their office and duty, according to ſtat. 43 Eliz. are principally theſe: firſt, to raiſe competent ſums for the neceſſary relief of the poor, impotent, old, and blind, and ſuch as are not able to work; and, ſecondly, to provide for ſuch as are able, and ſuch as cannot otherwiſe get employment: but this latter part of their duty, which, according to the wiſe regulations of that ſalutary ſtatute, ſhould go hand in hand with the other, is now moſt ſhamefully neglected. However, for theſe joint purpoſes, they are empowered to make and levy rates upon the ſeveral inhabitants of the pariſh, by the ſame act of parliament, which has been farther enforced and explained by ſeveral ſubſequent ſtatutes. (See RATE.) And by 17 Geo. II. cap. 38. if any perſon ſhall be aggrieved by any thing done or committed by the churchwardens and overſeers, or by any of his majeſty's juſtices of the peace, he may, giving reaſonable notice to the churchwardens or overſeers, appeal to the next quarterly ſeſſions, when the ſame ſhall be heard and finally determined: but if reaſonable notice be not given, then they ſhall adjourn the appeal to the next quarter ſeſſions; and the court may award reaſonable coſts to either party. By 43 Eliz. c. 2. the churchwardens and overſeers ſhall, within four days after the end of their year, and other overſeers nominated, make and yield up to two juſtices (1 Q.) a true and perfect account of all ſums by them received, or rated and aſſeſſed and not received, and alſo of ſuch ſtock as ſhall be in their hands, or in the hands of any of the poor to work, and of all other things concerning their office; and ſuch ſums of money as ſhall be in their hands ſhall pay and deliver over to their ſucceſſors: And the ſubſequent churchwardens or overſeers, by warrant from two ſuch juſtices, may levy by diſtreſs and ſale of the offender's goods the ſaid ſums or ſtock which ſhall be behind on any account to be made; and in defect of ſuch diſtreſs, two ſuch juſtices may commit him to the common gaol, there to remain without bail or mainprize, until payment of the ſaid ſum and ſtock: And alſo any ſuch two juſtices may commit to the ſaid priſon every one of the ſaid churchwardens and overſeers, which ſhall refuſe to account, there to remain, without bail or mainprize, until he have made a true account, and ſatisfied and paid ſo much as upon the ſaid account ſhall be remaining in his hands.

And by the 17 G. II. c. 38. it is enacted as follows: The churchwardens and overſeers ſhall yearly, within fourteen days after other overſeers ſhall be appointed, deliver in to the ſucceeding overſeers a juſt account in writing, fairly entered in a book to be kept for that purpoſe, and ſigned by them, of all ſums by them received, or rated and not received; and alſo of all materials that ſhall be in their hands, or in the hands of any of the poor to be wrought, and of all money paid by ſuch churchwardens and overſeers ſo accounting, and of all other things concerning their office; and ſhall alſo pay and deliver over all ſums of money and other things, which ſhall be in their hands, to the ſucceeding overſeers; which account ſhall be verified by oath before one juſtice, who ſhall ſign and atteſt the taking of the ſame at the foot of the account, without fee: and the ſaid books ſhall be preſerved by the churchwardens and overſeers in ſome public or other place within the pariſh or townſhip; and they ſhall permit any perſon aſſeſſed, or liable to be aſſeſſed, to inſpect the ſame at all ſeaſonable times, paying 6*d.* for ſuch inſpection; and ſhall, upon demand, give copies at the rate of 6*d.* for every three hundred words, and ſo in proportion. And if they ſhall refuſe or neglect to make and yield up ſuch account verified as aforeſaid, within ſuch time, or ſhall refuſe or neglect to pay over the money and other things in their hands; any two juſtices may commit them to the common gaol, till they ſhall have given ſuch account, or ſhall have paid and yielded up ſuch money and other things in their hands as aforeſaid.

And if any overſeer ſhall remove, he ſhall, before his removal, deliver over to ſome churchwarden or other overſeer his accounts verified as aforeſaid, with all aſſeſſments, books, papers, money, and other things concerning his office; and if any overſeer ſhall die, his executors or adminiſtrators ſhall, within 40 days after his deceaſe, deliver over all things concerning his office to ſome churchwarden or other overſeer, and ſhall pay out of the aſſets all money remaining due, which he received by virtue of his office, before any of his other debts are paid. 17 Geo. II. c. 38.

In caſe of an overſeer becoming a bankrupt, the balance of

of his account is not due till fourteen days after his year is expired.

Overſeers, neglecting their duty, ſhall forfeit for every default 20*s*. to the poor, to be levied by diſtreſs, or be committed to the common gaol. (43 Eliz.) And by 17 Geo. II. any pariſh officer, neglecting to obſerve the directions of that act, ſhall forfeit on conviction, within two calendar months after the offence committed, a ſum not exceeding 5*l*. nor leſs than 40*s*. to the poor, by diſtreſs. By 33 Geo. III. c. 55. neglect of duty or diſobedience to any lawful warrant or order of any juſtice, by any overſeer of the poor or other pariſh officer, upon complaint on oath, ſhall incur a fine, impoſed by two juſtices at any ſpecial or petty ſeſſions, not exceeding 40*s*., to be levied by diſtreſs, and applied to the uſe of the poor. Overſeers are indemnified in the performance of their duty by 43 Eliz. 1. Jac. c. 5. and 21 Jac. c. 12. the benefit of which latter ſtatute is extended by 26 Geo. II. c. 44.

Churchwardens by 43 Eliz. are called overſeers of the poor, and they join with the overſeers in making a poor rate, &c. But the churchwardens having diſtinct buſineſs of their own, uſually leave the care of the poor to the overſeers only; though anciently they were the ſole overſeers of the poor.

It ſeems not to have been determined whether a juſtice of the peace may be appointed overſeer. But it appears to be a prevalent opinion, that the offices of juſtice of the peace and overſeers of the poor are incompatible, becauſe the accounts of the latter were ſubject to the controul of the former.

By 1 W. & M. c. 18. Diſſenting teachers, qualifying themſelves according to the Toleration act, are exempted from being choſen or appointed to ſerve as overſeers. By 18 Geo. II. c. 15. freemen of the corporation of ſurgeons in London are alſo exempted; ſo is an alderman of London. The ſame is the caſe with reſpect to attornies and practiſing barriſters. It ſeems alſo that a clergyman is not liable to ſerve the office of overſeer, even though he have no cure of ſouls. An officer of the cuſtoms is alſo exempted; and it is ſaid, in Gibſon's Codex, 215, that all peers of the realm, by reaſon of their dignity, all clergymen, by reaſon of their order, and all parliamentary men, by reaſon of their privilege, are exempted from the office of churchwardens. See Poor.

OVER-SET, or Over-throw, in the *Sea Language*. A ſhip is ſaid to over-ſet when her keel turns upwards; which misfortune happens either by bearing too much ſail, or by grounding her, ſo that ſhe falls upon one ſide.

OVER-SWEAT, in *Agriculture*, a term ſometimes applied to hay-ſtacks, when they ſweat too much, ſo as to be liable to burn.

OVERT Act, a term in *Law*, ſignifying an *open act*; or an act capable of being manifeſted and proved.

The word is formed from the French *ouvert*, *open*.

In which ſenſe it is diſtinguiſhed from an *intentional act*. See Treason.

Overt *Market*. See Market.

Overt-*Pound*. See Pound.

Overt-*Word* denotes a plain open word, not to be miſtaken.

OVERTON, in *Geography*, a ſmall market-town and pariſh in the hundred of Overton, Kingſclere-diviſion, of the county of Southampton, England, is ſituated on the great weſtern road, at the diſtance of three miles E.N.E. from Whitchurch, and fifty-four miles W.S.W. from the metropolis. It was formerly a borough, and ſent two members to parliament, but loſt this privilege by neglect. The market day here is Monday, weekly, and there are three fairs during the year. The church is a neat building, ſeated on an eminence about a quarter of a mile from the centre of the town. This pariſh contains the tythings of Pollhampton, Quidhampton, and Southington; and is watered by a fine trout ſtream, which drives a ſilk mill, and ſeveral corn mills within the limits of the pariſh. Large quantities of malt are made here and in the adjoining villages. According to the population returns of 1811, the houſes in this pariſh were computed at 231, and the inhabitants at 1178, in number.

OVERTURE, in *Muſic*, the ſymphony in theatres, which immediately precedes the drawing up the curtain. It uſed to be called in France an *entrée*, and rendered as ſpirited, impoſing, and full of harmony, as poſſible. In Lock's Engliſh operas it is called a *curtain tune*.

French overtures, and indeed the firſt movements of thoſe of Handel, were almoſt all in the ſtyle of Lulli. They move in a ſpaſmodic and convulſive manner, bordering on bombaſt. Lulli's overtures have a ſlight fugue, always in triple time, after the opening, but no air. So that the overtures of Handel have no reſemblance to thoſe of Lulli but in the firſt movement; the ſecond is almoſt always an excellent fugue terminated by a pleaſing air in minuet, gavot, or jig time.

"There was a time when French overtures ſerved as models for all Europe. Sixty years have not elapſed, (ſays Rouſſeau,) ſince overtures were ſent for from France to place at the head of the Italian operas. I have even ſeen many ancient Italian operas in ſcore, with an overture by Lulli at its head. The Italians like not to hear this at preſent, but ſuch is the fact.

"Inſtrumental muſic having made an aſtoniſhing progreſs within theſe 40 years, (in 1768,) the old overtures made for performers not very well acquainted with the finger-board or the powers of their inſtrument, have been abandoned to the French, and they have continued to perſevere in them in their priſtine ſtate, without change or innovation. The Italians, impatient to ruſh forward in the road to fame, emancipated themſelves from gallic chains in muſic, however patiently they may have ſubmitted to political chains ſince, and compoſed overtures upon a different plan, full of fire and ſpirit in the firſt movement; in the ſecond generally a graceful and captivating *andante*, *ſempre piano*, in which they diſplay all the graces of a beautiful melody, &c.; laſtly, a brilliant *allegro*, commonly in $\frac{3}{8}$. The overture of this tune only acted as a crier of the court to enjoin ſilence by an *oyez*, by the time the curtain riſes, and the clattering of doors and ſtruggle for places ceaſe."

Overture *du livre*, or *à livre ouvert*, Fr., on the opening the book, at ſight; theſe are expreſſions applied to muſical ſtudents, or performers, who read muſic with as much facility as a newſpaper.

OVER-WORKED, in the *Manege*, is the ſame with over-done. It is called, in French, *eſtrapaſſer*.

OVER-WROUGHT, in *Rural Economy*, a term applied to horſes or other animals that are worked beyond their ſtrength.

OVER-YEARS, a provincial word applied to ſuch bullocks as are not finiſhed in fattening at three years old when home-breeds, or the firſt winter after buying in; but kept through the following ſummer to be finiſhed the next winter.

OVER-YSCHE, in *Geography*, a town of France, in the department of the Dyle, on the river Yſche; 10 miles S.E. of Bruſſels.

OUESSANT, or Ushant, an iſland in the Atlantic, belonging to France, about 10 miles in circumference, containing

taining ſeveral hamlets and a ſmall port, defended by a caſtle, and about 700 inhabitants; about 12 miles from the continent. N. lat. 48° 29′. W. long. 5°.

OUGEIN, Oogein, or *Oojein*, as variouſly ſpelled by different writers, is a city of India, the capital of the Mahratta chief Dowlut Rao Sindiah, in the province of Malwa, his hereditary territory. See Malwa.

This city is in many reſpects very intereſting, and our account of it will be ſomewhat particular, naturally dividing itſelf into a deſcription of the modern city, and a notice of the cataſtrophe, which at a remote period befel the ancient metropolis of Malwa. The preſent city of Oujein is of an oblong form, about ſix miles in circumference, and ſurrounded by a ſtone wall with round towers. Within this ſpace there is ſome waſte ground, but the inhabited part occupies by far the greateſt portion; it is much crowded with buildings, and is very populous. The houſes are built partly of brick, partly of wood. Of the brick houſes the frame is firſt conſtructed of wood, and the interſtices filled up with brick. They are covered either with lime, tarras, or with tiles. The principal bazar or market is a ſpacious and regular ſtreet, paved with ſtone. The houſes on each ſide are of two ſtories; the lower, to which you mount from the ſtreet by five or ſix ſteps, are moſtly built of ſtone, and is taken up with ſhops; the upper, of brick or wood, ſerve for the habitations of the owners.

The moſt remarkable buildings are four moſques, erected by private individuals, and a great number of Hindoo temples. Of the latter the moſt conſiderable is a little way out of the town, at a place called Unk-pat, held in great veneration, as being that where Kriſhna and his brother received the rudiments of their education. Here is a ſtone tank, with ſteps leading down to the water's edge, ſaid to be of great antiquity; but it has been of late years encloſed with a ſtone wall, and two temples have been erected within the incloſure. Theſe temples are ſquare, with pyramidal roofs. That on the right, as you enter the gate, contains the images of Rama, Lakſhiman, and Sita, in white marble; and that on the left, thoſe of Kriſhna and Radha, the firſt in black, the ſecond in white marble. All theſe figures are well executed. An account of theſe mythological perſonages is given in this work under their reſpective names.

Sindiah's palace in the city is an extenſive and ſufficiently commodious houſe, but without any claim to magnificence; and it is ſo cloſely ſurrounded by other buildings, as to make but little appearance on the outſide. Near it is a gate, the only remains of a fort, ſaid to have been built ſoon after the overthrow of the ancient city, which affords a good ſpecimen of the old Hindoo architecture.

Within the city, and near the eaſtern wall, is a hill of a conſiderable height, on the top of which is a Hindoo temple of Mahadeva, and adjoining to it the tomb of a Muſſulman ſaint. This hill is conſpicuous from a diſtance, and a ſpectator from the top of it commands an extenſive proſpect on every ſide. To the northward he ſees, at the diſtance of four miles, the rude and maſſy ſtructure of Kalideh, or Calydeh, an ancient palace, built on an iſland in the river Sipparah, by a king of the family of Gour. A deſcription of this extraordinary fabric is inſerted in the Oriental Repertory, vol. i. p. 266, from a letter of ſir C. W. Malet, dated Oujein, 13th of April 1785. By an extract from a hiſtory of Malwa, or Malava, theſe buildings appear to have been conſtructed by, or in the reign of, ſultan Naſir ud-deen Gilgee, who aſcended the throne of Malava in the year of the Hegira 905 (A.D. 1500), and reigned eleven years. Theſe ſingular buildings, we may judge from their name, were erected or conſecrated to the honour of

Kali, conſort of Mahadeva, (ſee thoſe articles,) to whom the temple on the hill within the city appears above to be dedicated. Theſe are two ſquare buildings, each covered with a hemiſpherical cupola, and divided below into eight apartments, beſides the ſpace in the centre. The communication to the iſland is by a ſtone bridge over one of the branches into which the river Sipparah is here divided. Below the bridge are ſeveral apartments conſtructed on a level with the water; and the rocky bed of the river is cut into channels of various regular forms, ſuch as circles, ſpirals, ſquares, &c. to which, in the dry ſeaſon, the current is confined. Turning to the weſtward, the ſpectator, from the top of the hill above-mentioned, traces the winding courſe of the Sipparah through a fertile valley, where fields of corn and clumps of fruit trees interſecting, diverſify the proſpect, till his attention is arreſted by the fort of Beiroungurh ſituated cloſe on the oppoſite bank. It is about a quarter of a mile in length, ſurrounded by a rampart of earth, and contains an ancient temple, dedicated to the tutelar divinity of the place, whoſe name it bears. Beiroungurh means the fort of Beiroun, or Bheroo, a Mahratta pronunciation of Bhairava, the offspring of Mahadeva. In the Sanſcrit language Bhairava means *tremendous*. Still farther up the ſtream, and nearly oppoſite to the middle of the town, are the gardens of two Mahratta nobles, containing the luxuries of nature with extenſive artificial decorations. Beyond theſe, at the diſtance of half a mile from the river, is a grove of trees on a riſing ground. It contains the tomb of a Mahomedan ſaint; and is remarkable for having been the ſcene of a bloody action, fought about the year 1762, between Sindiah and one of his rebellious officers, named Raghu, who marched to Oujein at the head of thirty thouſand men to attack his ſovereign with only five or ſix thouſand. With this inequality the fight began on the plain near the tomb above-mentioned, but Sindiah was joined by a party of ſix thouſand Goſains, (religious mendicants,) and a chance ſhot killing Raghu, the rebel party was wholly routed.

The proſpect on this ſide is bounded by a ridge of hills, at the diſtance of about three miles. It runs N.N.E. and S.S.W. and is ſeven miles in length. Theſe hills are chiefly compoſed of granite, and from them the ſtone employed in building is ſupplied; but they are covered with vegetable mould to a ſufficient depth to admit of cultivation. To the S.W. is a wide avenue of trees, which terminates a courſe of two miles, at a temple of Ganeſa, (a mythological ſon of Mahadeva, ſee Pollear,) ſurnamed Chintamun. It is viſited by numerous proceſſions at ſtated periods.

The ſouth wall of Oujein is waſhed by the Sipparah, which here makes a ſudden turning. This extremity of the city is called Jeyſing-poora, that is, the quarter of Jeyſing, and contains an obſervatory, built by the enlightened and liberal rajah of that name. He alſo built obſervatories at four other cities, *viz.* at Ambheer, his own capital, (ſince named from him Jeynagar,) Matra, Benares, and Dehli. He publiſhed, in 1728, a ſet of aſtronomical tables, which, in compliment to the then reigning emperor, he entitled Zij Mahommedſhahy. Of theſe five obſervatories, and the aſtronomical tables, and labours in that ſcience, of this illuſtrious prince the rajah Jeyſing, (or more correctly Jayaſinha,) a learned and very intereſting account is given in vol. v. of the Aſiatic Reſearches, by Dr. W. Hunter, from whoſe "Narrative of a Journey from Agra to Oujein," in vol. vi. of that work, this article is chiefly taken. See Observatory.

Turning to the left, we are preſented with a different proſpect.

proſpect. As far as the eye can reach is a level plain, which is only interrupted by a conical hillock, at the diſtance of three miles; beyond which is an extenſive lake, that lies cloſe on the road that leads to Bopal. On the right of the road, at the ſame place, is a park belonging to Sindiah, well ſtocked with deer.

The rajah Jeyſing held the city and territory of Oujein of the emperor, in quality of ſubahdar; but it ſoon after fell into the hands of the Mahrattas, and has belonged to the family of Sindiah for three generations (1813.) The diſtrict depending immediately on the city yields a revenue of five lacks of rupees (60,000*l.*) *per annum*, and comprehends 175 villages.

The officers of government are almoſt the only Mahratta inhabitants of Oujein. The bulk of the people, both Hindoos and Muſſulmans, ſpeak a dialect very little different from that of Agra and Dehli. The Muſſulmans form a very conſiderable portion of the inhabitants, and of theſe the tribe of Bohrah amount to about 1500 families. This ſingular tribe forms a large ſociety in moſt of the cities and large towns of Hindooſtan and the Deccan. Surat is ſaid to contain 6000 families. The head-quarters of the tribe are Burhanpoor, where their moulla or high prieſt reſides. A younger brother of the moulla reſides in Oujein. They exerciſe both a temporal and ſpiritual authority over their ſect, which forms the moſt uſeful and induſtrious claſs of the inhabitants.

The ſoil in the vicinity of Oujein, and indeed over the greateſt part of the province of Malwa, is a black vegetable mould, which, in the rainy ſeaſon, becomes ſo ſoft, that travelling is hardly practicable. On drying, it cracks in all directions, and the fiſſures are ſo wide and deep in many parts by the road-ſide, that it is dangerous for a traveller to go off the beaten tract; as a horſe, getting his foot into one of theſe fiſſures, endangers his own limbs, and the life of the rider. The quantity of rain that falls in ordinary ſeaſons is ſo conſiderable, and the ground ſo retentive of moiſture, that wells are rarely uſed for agricultural irrigation. A great part of the labour, incident to cultivation in other parts of India, is thus ſaved. But this very circumſtance makes the ſuffering more ſevere, on a failure of the periodical rains: for the huſbandman, accuſtomed to depend on the ſpontaneous bounty of heaven, is unprovided with wells, and is with difficulty brought to undertake the unuſual labours of irrigation, eſpecially as they muſt commence with digging the ſources.

There are, as in Hindooſtan, two harveſts in Malwa; the firſt in March and April, the ſecond in September and October. Wheat, peaſe, and various ſorts of vetches, ripen in the firſt. Barley is not cultivated, nor rice, otherwiſe than in ſmall detached low ſpots. Grapes are abundant. Oujein is firſt ſupplied from Burhanpoor, a very large and flouriſhing town, more than 100 miles to the ſouthward.

By the time the Burhanpoor grapes are exhauſted, in April, thoſe of Oujein ripen, but are inferior to the former. The vines produce a ſecond crop in the rainy ſeaſon, but of an acidulous and much inferior grape. The other fruits are the mango, guava, plantain, melon, water melon, two ſpecies of annona (ſquamoſa and reticulata), ſeveral varieties of oranges and limes, the falſah (Grewia aſiatica), from which is made a moſt refreſhing ſherbet, ſlightly acidulous.

The principal articles of export trade are cotton, which is ſent in large quantities to Guzerat for the Bombay and China market, coarſe printed cloths, and opium. From Bombay, through Surat, are received various kinds of Europe and China goods, many of which are ſometimes to be purchaſed cheaper in Oujein than in the Engliſh ſettlements; alſo pearls, which are partly uſed here, and partly forwarded to Hindooſtan. Aſafœtida, which is produced in Sind and provinces beyond it, comes hither on its way to the eaſtward, to Mirzapoor, &c.; and diamonds, from Bundelcund to Surat.

The following obſervations on the weather at Oujein were made by Dr. Hunter in 1792. In the months of April and May, the winds in the day-time were ſtrong and hot; the thermometer expoſed to them being from 93° to 109°, at P.M. Theſe winds, with little deviation, come from the weſtward. The heat at 9 P.M. varied from 80° to 90°. The mornings were more temperate, in one inſtance only riſing ſo high as 81°, and ſometimes being as low as 69°. From the 18th to the 25th of May, we had frequent ſqualls from the N.W. and W.N.W.; once from N.E., with thunder, lightning, and rain. The quantity of rain that fell in this time was about 10 inches. This weather is not uſual at this ſeaſon: it produced a temporary coolneſs; but the ſky clearing up before the end of the month, the air returned to its former temperature, and even exceeded it, for the morning heat now ſometimes roſe to 85°.

On the 11th of June, the rains ſet in, and the quantity that fell during the ſeaſon was as follows:

May, as above, about	10 inches,	rained 5 days.
June,	3.521	9
July,	12.071	22
Auguſt,	21.088	22
September,	5.651	9
	52.331	67

The rain terminated on the 14th of September. From the middle of June to the middle of July, the afternoon heat varied from 107° to 86°, gradually diminiſhing as the ſeaſon advanced, and ſometimes, from the continuance of the rain, was as low as 80°. The morning was more uniform; its extremes being between 87° and 77°; the evening between 90° and 75°. The weather during this period was conſtantly cloudy, ſometimes hazy; wind uniformly from the weſtward, ranging from N.W. to S.W.

From the middle of July to the termination of the rains, the afternoon heat was from 89° to 74°. The limit between the two periods was ſtrongly marked; July the 15th at P.M. being 91°, and on the next day, at the ſame time, 78°; the morning from 80° to 72°. During this period, the clouds were ſo heavy, and ſo uniformly ſpread over the face of the heavens, that the ſun could ſeldom dart a ray through the gloom. The rain was frequent, and long continued, but ſeldom heavy. The only inſtance in which the rain of one day amounted to ſo much as three inches was between 7 P.M. of the 15th of Auguſt, and 9½ A.M. of the 16th. During this period of 26½ hours, the rain was inceſſant, and the quantity amounted to 10.128 inches. It then abated, but did not ceaſe till the 17th, at 4 P.M.: the quantity in that interval was 0.629. So great a fall of water cauſed a deſtructive inundation. The waters continued to riſe till the 16th at midnight, and then gradually ſubſided; but it was ſeveral days before the river was fordable by men or horſes.

During the rainy ſeaſon, the prevailing wind is weſterly, ranging from N.W. to S.W.; a few times light winds from the S. and from the E.

After the rains were over (14th September), the ſky cleared up, and the mid-day and afternoon heat increaſed. By the 23d, it was 92°; October 1ſt, 101°; and till the middle of November, was ſeldom under 90°. The morn-

ing heat, during that period, gradually decreaſed from 73° to 46°; the evening from 79° to 57°. The dew latterly very heavy.

The winds continued for two days (14th and 15th Sept.) at W. To the end of the month calm, or light airs from the N.E. To the middle of October, winds of moderate force from the N.W. prevailed; but with frequent calms. N.E. to the end of the month, with hazy mornings. All October there was not a cloudy day. In November, till the 6th, weſterly was the reigning wind; to the 15th the N.E. recovered its prevalence; to the 8th the days were hazy; on the 4th a little rain fell. For the next week the ſky was clear. At this time this accurate obſerver (Dr. Hunter) was ſeized with a fever, which ſuſpended his meteorological remarks till the 1ſt of February. All he could notice was ſtormy weather about the middle of December, with thunder and a pretty heavy fall of rain.

From the 1ſt of February to the 14th of March, when Dr. Hunter left Oujein, the afternoon heat varied between 73° and 103°. The firſt on the 9th February with wind at N.N.W.; the higheſt 12th March, wind W. ſky at both times clear. Morning heat from 46° to 67°; evening from 55° to 76°.

The weſterly were the prevailing winds during this period, ranging from N.N.W. to S.S.W. In February an eaſterly wind was obſerved twice in the morning, four times at midday, and twice in the evening. It did not occur again to the 14th of March. A ſmall ſhower of rain fell on the 4th of February, and this was the only cloudy day during the period in queſtion.

The foregoing abſtract gives a pretty clear idea of the weather at Oujein for a year. But we are cautioned by the author of it not to conſider it as an exact eſtimate of the weather uſually experienced there. The quantity of rain, in particular, he repreſents as far exceeding the uſual fall. On this we have to obſerve, that although for a day and night, as particularly mentioned, the fall was, indeed, exceſſive, yet for the whole period of the rainy ſeaſon, we do not conſider the depth given as any *very* exceſſive or unuſual fall. This we ſay on the authority of ſome meteorological journals in MS. to which we have had acceſs, and with which we have compared Dr. Hunter's. The degree of extreme heat, too, is greater than we have noticed elſewhere, in the weſtern parts of India in the rainy ſeaſon. Making ſome abatement on theſe two items (the fall of water and the extreme of heat), we are diſpoſed to think the above a fair ſpecimen of the climate of the weſtern parts of India above the Ghauts, from Oujein to Seringapatam. It muſt be recollected, however, that the rains uſually ſet in about a month earlier in the ſouthern, than in the northern parts of that range. Fevers, chiefly intermittent, prevailed at Oujein toward the end of the rains, and increaſed in frequency till the middle of November. Theſe were imputed to local and temporary cauſes; and the only endemic obſerved by Dr. Hunter, was the dracunculus, or Guinea worm.

The ſituation of this city is of importance, as it is conſidered as the firſt meridian by Hindoo geographers and aſtronomers. (See LANKA.) By the medium of eleven obſervations of Jupiter's firſt and ſecond ſatellites, Dr. Hunter determined its long. to be 75° 51′ E. from Greenwich. Its lat. by a med. of eight obſ. he made 23° 11′ 13″ N. It may be roundly reckoned about 300 miles N.E. from Surat, ſomething more ſouth from Agra. Indore, the capital of the Mahratta family of Holkar, is about 20 miles in a ſoutherly direction, and Bopal (properly Bhùpàla) about 100 to the eaſtward. The laſt named is a flouriſhing town and diſtrict, ruled by a Mahommedan government and dynaſty, in a manner apparently more independent of the Mahrattas, than is uſual in towns or diſtricts ſimilarly ſituated. We ſhall conclude this lengthened account of the modern city of Oujein, by obſerving, that during the military operations carried on under the adminiſtration of the marquis Welleſley, againſt the Mahratta confederates, the Bombay army, under general ſir John Murray, took poſſeſſion of both Indore and Oujein. But although we retained the latter city for ſome months, we have not heard of any literary reſult from our poſſeſſing ſo curious and intereſting a ſpot. It ſeems to be within the reach of the literary ſocieties both of Calcutta and Bombay, and conſidering our extended connection and intercourſe with the Durbar, and country of Dowlut Rao Sindiah, a reaſonable hope may be entertained of due notice being attracted to a ſpot promiſing ſo abundant a recompence to well-directed enquiry and reſearch.

The ancient city of Oujein was ſituated about a mile to the northward, and now lies, and has for many centuries lain, buried in the earth to the depth of from fifteen to eighteen feet. On digging, its walls are ſaid to be found entire, pillars erect and unbroken, pieces of wood of extraordinary hardneſs, &c. The bricks thus dug up are now applied to the purpoſes of building, but are much larger than any made in the preſent or late ages. Utenſils of various kinds have been found, and ancient coins. Very little, however, has been yet done towards developing the preſent ſtate of this ſubmerged city; the intereſting Herculaneum of India. Dr. Hunter noticed a large quantity of wheat that was found while he was there; it was in a charred ſtate; a potter's kiln he alſo ſaw, filled with broken earthen veſſels. Tradition imputes the deſtruction of the city to a ſhower of earth, an idea likely to have originated in ſuperficial obſervation; for although Dr. Hunter obſerved no volcanic hills, nor ſcoria, in the neighbourhood, and thinks the ſtate and poſition of the walls and pillars militate againſt the ſuppoſition of an earthquake having effected the ſubmerſion of the city, it is here difficult to impute it to any other than a volcanic cauſe, operating, perhaps, with leſs violence and convulſion than have attended ſimilar phenomena in other countries, and combined with, or rather cauſing, an inundation of the river. A change in the courſe of the river is ſaid to have taken place at the time, and an ancient bed is now traceable. A deſtructive inundation was witneſſed and recorded by Dr. Hunter; and the writer of this article knows of another that occurred in a late rainy ſeaſon. It would appear that the neighbourhood of Oujein is particularly ſubject to inundation, and when the looſe friable nature of the ſoil be conſidered, it ſeems moſt reaſonable to reſort to an alluvial hypotheſis to account for the ſubmerſion of the ancient city. But whatever may have been the real cauſe of the cataſtrophe, it cannot be ſuppoſed that the wild fancies of Hindoo hiſtorians would ſuffer the fact to be ſimply told. It muſt be dreſſed up in a mythological allegory. In fable or fact the interventions of the gods cannot be diſpenſed with. The following ſtory is accordingly related.

A certain Gandharva, or celeſtial choriſter, was condemned for an affront to the god Indra, to be born on earth in the ſhape of an aſs; but on entreaty the ſentence was mitigated, and he was allowed at night to aſſume the form and functions of a man. This incarnation took place at Oujein in the reign of rajah Sadaſvaſena, whoſe daughter was demanded in marriage by the aſs; and his conſent was obtained, on learning the divine origin of his intended ſon-in-law, confirmed, as he witneſſed, by certain prodigies. All day he lived in the ſtables like an aſs; at night, ſecretly ſlipping out of his ſkin,

ſkin, and aſſuming the appearance of a handſome and accompliſhed young prince, he repaired to the palace, and enjoyed the converſation of his beauteous and happy bride.

In due time the princeſs became pregnant; and her chaſtity being ſuſpected, ſhe revealed to her inquiſitive parents the myſtery of her ſpouſe's delectable nocturnal metamorphoſis; which the rajah, (or by other accounts the mother,) being conveniently concealed, himſelf beheld; and unwilling that his ſon ſhould return to his uncouth diſguiſe, ſet fire to, and conſumed, the vacant aſſes' ſkin.

Rejoiced at his releaſe, for this event appears to have broken the ſpell, the incarnate Gandharva warned his beloved wife to quit the city, which he foreſaw was about to be overwhelmed with a ſhower of earth from the reſentment of Indra, thus diſappointed of his vengeance in the termination of the baniſhment of his inſolent ſervant. She fled accordingly to a village at a ſafe diſtance, and brought forth a ſon named Vikramaditya; and a ſhower of cold earth, poured down by Indra, buried the city and its inhabitants.

It may be here noticed that this fable, wild as it is, affords ſtill ſome confirmation of the ſuppoſition of an inundation during the rainy ſeaſon having deſtroyed the city. For Indra is the god of ſhowers, and ſuch an event would of courſe be attributed to the vengeance of the Jupiter Pluvius of the Hindoo Pantheon, in the ſame manner as we frequently find the caſe in the natural phenomena mythologized in the Iliad. See INDRA.

The ſeeming fable has, alſo, another feature of hiſtoric truth; for Vikramaditya, ſo diſtinguiſhed in his origin and birth, is no leſs ſo as a monarch and an aſtronomer. His name marks an era much uſed all over India, of which the 1869th year correſponds with 1813 of our's. Several monarchs of Malwa of this name are however recorded; and differences of opinion exiſt on ſome chronological points connected with this era. (See Aſ. Reſ. vol. ix. art. iii.) The Vikrama in queſtion is, however, particularly diſtinguiſhed by the ſurname of his putative parent, who is called Gardha-rupa, or the aſs-faced, and his era is hence to be aſcertained with more accuracy than is uſually obtainable on remote points of Hindoo chronology. He was the third Vikramaditya, and appears, by ſeveral hiſtorical coincidences, to have aſcended the throne of Malwa in the year of Chriſt 441. It hence appears that the city ſunk about 1400 years ago. The ſtory of the aſs, variouſly modified, is widely ſpread in the popular tales of India, Perſia, Turkey, Arabia, and other oriental countries, and has found its way even into the literature and legends of Europe.

The claſſical name of this city is Ujjaini, not materially altered in its preſent deſignations. It is alſo called Avanti in the Puranas, is much venerated by the Hindoos, and is one of the moſt celebrated for producing great and learned men among the cities of India. If Benares has been thought to deſerve the name of the Athens, Oujein may lay claim to the honour of being the Florence of Hindooſtan. From this circumſtance we have been induced to be more diffuſe than is uſual with us in like caſes, in our account of this city, which, and the legends connected with it, furniſh ample ſubjects for the deſcriptive and fabulous details of Puranic romance. From this ſource we ſhall notice one more tale, or rather a variation of that already given, accounting for one of the ancient names of the city; premiſing, however, that ſuch tales being found in the Puranas, fully prove thoſe books, a portion of them at leaſt, to have been written ſubſequent to the cataſtrophe that they deſcribe. See PURANA.

The varied legend to which we advert, ſays that the curſe having expired in the conſumption of his aſinine diſguiſe, the Gandharva aſcended to the heaven of Indra; and that his wife, reſolving to die, ripped open her belly, took out the child, and gave it to a *malini* (gardener's wife) to nurſe. She took it to Ujjaini, and from the ſignal preſervation of the child in that city, it obtained the name of Avanti, from the Sanſcrit *ava*, to preſerve. Kriſhna is ſtated to have been educated, and his friend Narada to have been born, in Avantipuri.

The city of Oujein appears evidently, both as to name and poſition, in the Periplus of the Erythrean ſea, as well as in Ptolemy, under the name of "Ozena."

OUGHTER LOUGH, a lake of the county of Cavan, Ireland, formed by an expanſion of the river Erne, which flows through it. The irregularity of its form, the large and beautiful iſlands it contains, and the many deep receſſes that wind between high banks and overhanging woods, produce a rich variety of intereſting and romantic ſcenery. It was in a ſmall iſland in this lake that good biſhop Bedel was confined by the inſurgents in the ſeventeenth century. Beaufort.

OUGHTERARD, a ſmall poſt-town of Ireland, in the county of Galway, ſituated on lough Corrib. The rocks here are of black and white marble. It is 120 miles W. by N. from Dublin, and nearly 14 miles N.W. from Galway.

OUGHTRED, WILLIAM, in *Biography*, an eminent mathematician, was born at Eton, in Buckinghamſhire, about the year 1573. He was educated in grammar learning upon the foundation of that ſchool, and was thence elected, in 1592, to King's college, Cambridge, of which he was afterwards admitted a fellow. Here he applied himſelf with great aſſiduity to the ſtudy of different branches of academical learning, and particularly that of mathematics. While an under-graduate, he invented "An eaſy method of geometrical dialling," which was not publiſhed before the year 1647, but was privately received with ſo much eſteem, that Mr. (afterwards ſir Chriſtopher) Wren, at that time a ſcholar of Wadham college in Oxford, immediately tranſlated it into the Latin language. In 1596 Mr. Oughtred was admitted to the degree of B.A., and in 1599 to that of M.A. About the year 1603 he was ordained prieſt, and preſented with the rectory of Aldbury, near Guilford, in Surry, upon which he quitted the univerſity, and reſided upon his living, diſtinguiſhing himſelf by the faithful and diligent diſcharge of his paſtoral duties. Here he led a retired and ſtudious life, ſeldom travelling ſo far as the metropolis, his principal recreation conſiſting in a diverſity of ſtudies. So high was his reputation for mathematical knowledge, that he obtained what number of pupils he pleaſed, and many of the chief mathematicians of that age owed much of their ſkill to him. He alſo maintained a correſpondence with ſome of the moſt eminent ſcholars of his time on mathematical ſubjects. In the year 1614, Mr. Briggs, profeſſor of geometry, having met with lord Neper's account of the invention of logarithms, and deſigning to perfect the plan, conſulted Mr. Oughtred upon the ſubject, who probably wrote his treatiſe "On Trigonometry" about this time, though it was not publiſhed till 1657. In proſecuting the ſame ſubject, he invented, not many years afterwards, an inſtrument called "The Circles of Proportion," by which all ſuch queſtions in arithmetic, geometry, aſtronomy, and navigation, as depended upon ſimple and compound proportion, might be worked; and it was the firſt ſliding-rule that was projected for thoſe uſes, as well as thoſe of gauging. In 1628 Mr. Oughtred was engaged by the earl of Arundel to become mathematical tutor to his ſon lord William Howard, and

and he drew up for the uſe of his noble pupil "Arithmeticæ in numero et ſpeciebus Inſtitutio; quæ tum Logiſticæ, tum Analyticæ atque adeo totius Mathematicæ quaſi Clavis eſt," which he publiſhed in 1631. This work, which was intended by the author to ſerve as a general key to the mathematics, was very favourably received both at home and abroad. An Engliſh tranſlation of it was publiſhed in 1647, under the title of "The Key of the Mathematics new forged and filed, &c." It went through ſeveral editions, and became a ſtandard work with tutors in the inſtruction of mathematical pupils at the univerſities, and ſome parts of it were made the ſubjects of the geometrical lectures at Greſham college. In a third edition of his Clavis, he added a treatiſe on the uſe of logarithms; a declaration of the tenth book of Euclid's Elements; a treatiſe of regular ſolids, and the theorems contained in the books of Archimedes. He did not think it neceſſary, nor of any advantage to geometry, abſolutely to confine the demonſtrations, in the ſublimer parts of ſcience, to the principles laid down in the Elements. On the contrary, in his expoſitions of the theorems of Archimedes on the ſphere and cylinder, he condemns the rigid ſtrictneſs of that author, which obliged him to make uſe of arguments ex abſurdo. Theſe he rejected, and aſſuming for a poſtulatum, that a circle is a plane, and a ſphere a ſolid figure having an infinite number of ſides, he gives, for the moſt part, affirmative and direct demonſtrations of thoſe theorems. Notwithſtanding all his mathematical merit, he was in danger, about the year 1646, of a ſequeſtration by the committee for plundered miniſters, ſeveral articles having been depoſed and ſworn againſt him; but upon the day of hearing, William Lilly, the famous aſtrologer, applied to all his friends, who appeared in ſuch numbers on his behalf, that though the chairman and many members were active againſt him, he was acquitted. He died in 1660, at the good old age of 86, and his death was ſaid to have been occaſioned by a ſudden exſtacy of joy, upon hearing the vote which was paſſed at Weſtminſter for the reſtoration of Charles II. He has been characteriſed "as facetious in Greek and Latin; as ſolid in arithmetic, aſtronomy, and the ſphere of all meaſures, muſic, &c.; exact in his ſtyle, as in his judgment; handling his cube, and other inſtruments at eighty, as ſteadily as others at thirty; owing, he ſaid, to temperance and archery; principling his people with plain and ſolid truths, as he did the world with great and uſeful arts; advancing new inventions in all things but religion, which, in its old order and decency, he maintained ſecure in his privacy, prudence, and contentment." He had a ſon, whom he put apprentice to a watchmaker, for whom he wrote a book of inſtructions in that art. He left behind him a great number of manuſcripts upon mathematical ſubjects, and moſt of his Greek and Latin books contained notes in his own hand writing, with a demonſtration of the propoſitions in the margin. Theſe books and manuſcripts came into the poſſeſſion of Mr. William Jones, father of the late ſir William Jones, and afterwards into the hands of ſir Charles Scarborough, the phyſician, who carefully ſelected thoſe that were fit for the preſs, and printed them in 1676, under the title of "Opuſcula mathematica hactenus inedita," 8vo. Biog. Brit.

OUGLY, in *Geography*, a town of Hindooſtan, in the circar of Sanore; 75 miles W. of Sanore.

OUGUELA, a town of Portugal, in the province of Alentejo; ſix miles S. of Albuquerque, in Spain. N. lat. 38° 54′. W. long. 6° 43′.

Ouguela, a town of Africa, in the territory of Tripoli. See Aguila.

OVICULUM, in the *Ancient Architecture*, a little *ovum*, or egg.

Some alſo uſe the word *oviculum* for *ovolo*.

Baldus will have this to be the Leſbian aſtragal of Vitruvius. Daviler

OVID, Publius Ovidius Naso, in *Biography*, a celebrated Roman poet, was born at Sulmo, the preſent Abruzzo, in the conſulate of Hirtius and Panſa, in the year 43 B.C. He was of an ancient equeſtrian family, and was ſent in his youth to Rome to be educated in liberal ſtudies under the beſt maſters: he ſhewed a propenſity to poetry at an early period of his life, and it was not without extreme difficulty, that his father could prevail on him to relinquiſh the culture of the Muſes for the thriving purſuits of the law. At length, however, he was prevailed on to ſet down to buſineſs, and he appears to have made good progreſs in forenſic eloquence and judicial knowledge, for he refers to ſome cauſes that he had pleaded with great ſucceſs; and he afterwards ſat as one of the triumvirs to whom criminal juriſdiction was committed. By the death of his brother he was probably no longer obliged to follow the law as a gainful profeſſion, deſerted the courts, and gave himſelf up to pleaſure and poetry. His talents and amiable qualities introduced him to the beſt ſociety in Rome. He was married three times; from the firſt two wives he was divorced, but he ſpeaks of his third, Perilla, with great affection, by whom he had a daughter, who adhered to him in all his fortunes, and who is thought to have ſurvived him. He ſeems to have lived at his eaſe and in affluence, poſſeſſing a houſe near the capitol, and pleaſant gardens on the Appian way, as well as a villa in his native country. A lively genius and a fertile imagination gained him many admirers; Virgil, Propertius, Tibullus, and Horace, honoured him with their correſpondence, and Auguſtus patroniſed him with the moſt unbounded liberality. He had rendered himſelf famous by ſeveral poetical compoſitions, when, at about the age of fifty, he incurred a ſentence of baniſhment, which was never revoked, and which made him an exile for the remainder of his life. The true cauſe of this circumſtance has never been known. Few incidents in claſſical biography have more excited the diſcuſſion of the curious than this; ſtill a myſtery hangs upon it which no elucidation can thoroughly clear. He has himſelf aſſigned two reaſons for the anger of Auguſtus; one, and that the oſtenſible cauſe, though certainly not the true reaſon, the licentiouſneſs of his juvenile poems; the other, he ſays, was an error, not a crime, ſomething of which his eyes had been guilty, not his intentions:

> "Inſcia quod crimen viderunt lumina plector,
> Peccatumque oculos eſt habuiſſe meum."

And in another places he writes,

> "Perdiderunt cum me duo crimina, carmen et error
> Alterius facti culpa ſilenda mihi eſt."

It was ſomething in which the emperor's feelings were particularly concerned; ſome attribute it to an amour of Ovid with Livia, the wife of Auguſtus, while others ſuppoſe it aroſe from the knowledge which the poet, involuntarily, had of the ſhocking inceſt of the emperor with his daughter Julia. The place of Ovid's exile was Tomi, a town in Scythia, near the Euxine ſea, and not far from the mouths of the Danube. His elegiac epiſtles from that place are full of complaints of the ſeverity of the climate, the wildneſs of the ſcenery, and the ſavage manners of the ſurrounding people. How long he lived in this condition is not certainly known; he was alive in the eighth year of his exile, which was two years after the death of Auguſtus. That event

event had no effect in producing his recall, for Tiberius was either hoſtile or indifferent to him. He felt moſt bitterly this perpetual excluſion from cultivated life, and all the conſolations of friendſhip and domeſtic affection, and does not affect a ſtrength of mind which did not belong to his character. The Euſebian chronicle places his death in the fourth year of Tiberius, but the authority cannot be relied upon. The people of Tomi are ſaid to have mourned publicly for him, and to have erected a ſtately monument to his memory without the walls of their city. Ovid was a copious writer, and the greater part of his works has come down to our times. Thoſe which we poſſeſs are his "Heroical Epiſtles," compoſed in the characters of diſtinguiſhed lovers in the heroical ages; his elegies entitled "Amorum," and books on the "Art of Love;" his fifteen books of "Metamorphoſes;" his ſix books of "Faſti" on the Roman calendar, which are only half the number that he compoſed; his elegiac lamentations entitled "Triſtia," and "Epiſtolæ ex Ponto." Beſides theſe there is his "Ibis," written in imitation of a poem of Callimachus of the ſame title, which is a ſatyrical performance: there are alſo fragments of other poems, among theſe ſome of a tragedy entitled "Medea." The loſs of half the "Faſti" is to be greatly regretted, as it is probable it contained much valuable and intereſting information reſpecting the religious antiquities of the Romans. The tragedy of "Medea" was regarded as one of the beſt productions of the Roman theatre. On whatever he has written, he has totally exhauſted the ſubject. He ever paints nature with a maſterly hand, and gives ſtrength to the moſt vulgar expreſſions. "There is no ſubject, which in his hands he does not turn into poetry, or, at leaſt, into elegant verſe. His vein is inexhauſtible; and his principal faults ariſe from that ſuperabundance of wit and fancy, which is apt to run him out of breath, while he chaſes one thought or image after another. He abounds beyond any other ancient with points and turns of expreſſion ſometimes really beautiful and ſtriking, often deviating into trifling puerility. In his happieſt moods, he deſcribes with wonderful force and vivacity; he is ſometimes ſplendid and pictureſque, ſometimes elegantly chaſte and ſimple. With all his tendency to ſuperfluity, no one has exceeded him in the neat and energetic brevity with which he occaſionally gives a moral ſentiment, ſo that his works are an admirable ſtore of mottos and ſentences. He is ſometimes, though rarely, ſublime, often brilliant, frequently pathetic, and almoſt always amuſing. If he does not rank with the very firſt claſs of poets, he is certainly one of the moſt agreeable." The editions of the whole, and of detached parts of his works, have been extremely numerous. The following have been mentioned as among the moſt valuable of the whole works; that of Heinſius, Elzevir, 3 vols. 12mo. 1629; Burman's, Amſt. 4 vols. 4to. 1727; and of Utrecht, 4 vols. 12mo. 1713; Wetſtein's Amſt. 3 vols. 12mo. 1751; Barbou's, Paris, 3 vols. 12mo. 1762; and Fiſcher's, Lipſ. 4 vols. 8vo. 1773.

Ovid, in *Geography*, a poſt-town of New York, in Cayuga county, incorporated in 1794, and containing 2169 inhabitants.

OVIEDA, in *Botany*, received that name from Linnæus, in honour of Gonſalvo Ferdinando d'Oviedo, alias de Valde, a Spaniſh divine, who in the reign of Ferdinand V. was ſuperintendant of the gold mines of South America, and reſided at Santa Maria in Darien, of which he was rector. He wrote a hiſtory of the Weſt Indies, containing an account of many American plants; which may be ſeen in the collection of Voyages, publiſhed by the Giunti, at Venice, in 1556, and which is taken from the Spaniſh edition, printed at Toledo in 1526. Of this there are Engliſh, Italian, and French tranſlations. Plumier, who firſt eſtabliſhed the preſent genus, called it *Valdia*, which Linnæus properly corrected.—Linn. Gen. 325. Schreb. 425. Willd. Sp. Pl. v. 3. 381. Mart. Mill. Dict. v. 3. Juſſ. 211. Lamarck Illuſtr. t. 538. Gærtn. t. 57. (Valdia; Plum. Gen. 11. t. 24.)—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Caprifolia*, rather *Vitices*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, erect, in five ſhort, broadiſh, acute, permanent ſegments. *Cor.* of one petal, ringent; tube extremely long, narrow, nearly cylindrical; limb ſhort, in five (not three), nearly equal, obtuſe ſegments. *Stam.* Filaments four, thread-ſhaped, longer than the corolla, incurved at the ſummit, two of them rather the longeſt; anthers roundiſh. *Piſt.* Germen ſuperior, globoſe; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma in two acute ſegments. *Peric.* Berry nearly globoſe, four-lobed, of one cell, ſeparable into four parts, ſtanding upon the enlarged calyx. *Seeds* four, tumid on one ſide, angular on the other, of one cell.

Eſſ. Ch. Calyx five-cleft. Corolla with a very long cylindrical tube; limb five-cleft, nearly equal. Berry globoſe, with four ſeeds.

1. O. *ſpinoſa*. Spinous, or Weſt Indian, Ovieda Linn. Sp. Pl. 888. Swartz Obſ. 248 (Valdia cardui folio, fructu ſubcæruleo; Plum. Ic. 254. t. 256.)—Leaves elliptical, with ſpinous teeth.—Native of Hiſpaniola. Our ſpecimen was gathered by Von Rohr in that iſland, near the town called *aux Cayes*, and communicated by ſir Joſeph Banks. Linnæus had never ſeen this plant, which is one of the rareſt productions of the Weſt Indies. The *ſtem* is ſhrubby, with rough branches. *Leaves* oppoſite, on ſhort, round, downy *footſtalks*, elliptical or obovate, acute, rigid, four or five inches long and two broad; ſmooth above; reticulated with numerous ſtrong veins beneath; bordered with broad, unequal, ſpinous teeth. *Panicle* terminal, erect, corymboſe, ſomewhat leafy, its ſtalks oppoſite, three-cleft, downy. *Bracteas* lanceolate, deciduous. *Calyx* hairy, with ten ſtrong ribs, and five ſpinous, ſpreading, not very deep, teeth. *Corolla* three inches long, downy, apparently white with a purple tinge, or perhaps entirely purple when freſh, the limb in five, nearly equal, obtuſe, ſpreading, downy-edged ſegments, each above half an inch long. Plumier ſays the ſegments are generally but three. His deſcription of the inſertion of the *corolla* upon an inner calyx, is unintelligible to us, and we preſume he means that the globular baſe of the *tube* cloſely envelopes the *germen*. He deſcribes the *fruit* as blueiſh; Swartz ſays it is black, ripening in May.

2. O. *mitis*. Smooth, or Eaſt Indian, Ovieda. Linn. Sp. Pl. 889. Burm. Ind. 136. t. 43. f. 1.—Leaves linear-lanceolate, wavy, entire.—Native of Java. A ſmooth and unarmed *ſhrub*. *Leaves* four in a whorl, nearly ſeſſile, five or ſix inches long, not an inch wide, acute, entire, thick-edged, ſlightly wavy, ſmooth, with many curved inter-branching veins. *Stipulas* awl-ſhaped, minute, within the footſtalks. *Panicle* large, leafy, terminal, of numerous, three-forked, axillary and terminal, ſmooth branches. *Bracteas* lanceolate or linear, ſmooth. *Calyx* ſomewhat glutinous, unarmed. *Corolla* as long as the former ſpecies, rather downy upwards; its limb in five obtuſe, concave, nearly equal ſegments, laterally overlapping each other in the bud. Their colour ſeems to be white or yellowiſh, with ſtains of red or purple. It is remarkable that Burmann repreſents the corolla of this with only three ſegments. Perhaps he ſaw but a bad dry ſpecimen, and truſted to Plumier and Linnæus for the generic character. The *leaves* are whorled in Linnæus's own ſpecimen, though he deſcribes them

them as oppoſite, and has led ſome botaniſts to think the whorled plant a new ſpecies. *O. mitis* is the only ſpecies he ever ſaw, even in a dried ſtate.

OVIEDO, ANDRES DE, in *Biography*, biſhop of Hieropolis, and patriarch of Ethiopia, was born at Ilhecas, a town ſituated half way between Madrid and Toledo. He graduated at Alcala, and then went to Rome, where, in the year 1541, he entered the ſociety of Jeſuits, then only in its infancy. When Joam III. founded the firſt Jeſuit college at Coimbra, he, with eight Flemiſh companions, was ſent to colonize it by Peter Faber. Oviedo ſoon diſtinguiſhed himſelf by his devotion, his humility, and ſelf-auſterity, and was nominated rector of a college at Gandia. He was afterwards made rector of the college at Naples: in theſe ſituations he performed the duties required of him with exactneſs, and inflicted upon himſelf the moſt ſevere mortifications. "Thus far," ſays Mr. Southey, "his talents had been well employed; but when Loyola nominated him as coadjutor and ſucceſſor to Joam Nunez Bareto in the Abyſſinian miſſion, he miſtook the character of Oviedo. A ſtateſman was wanted, not a fanatic." He was conſecrated biſhop of Hieropolis, and with oſtentatious humility he uſed to fetch water for the college. In 1556 he and Bareto ſet ſail, and reached Goa in little more than four months. The affairs of Abyſſinia at this time were in ſo unproſperous a ſtate, that it was not thought expedient for the patriarch to proceed thither; he was therefore detained at Goa, while Oviedo, with his five companions, was ſent forward on the miſſion. They landed at Arkeeko five days only before that fort was taken poſſeſſion of by the Turks. On his way to court, Oviedo was welcomed by the Portugueſe, and received with every mark of reſpect and honour: but he was outrageous againſt the reigning prince, who would not change his creed, and threatened to excommunicate all who remained in his ſervice. He himſelf would have returned to India, but was perſuaded by his countrymen, who were ſettled in Abyſſinia, not to leave them. At length Oviedo and the other Jeſuits excited a rebellion in the country, and though they were ſucceſsful in their attempts to injure and haraſs the exiſting government, yet their ſtay in the country was thought ſo fruitleſs, that orders came from Rome for them to go to Japan. By the death of Bareto, Oviedo had now ſucceeded to the vain title of patriarch, but now he had no poſſible means of getting away from Abyſſinia, and ſo completely deſtitute was he of all European conveniences, that the letter which he contrived to ſend to Rome was written upon ſlips of paper cut from the margin of his breviary. He lingered out the remainder of his days in obſcurity, and died in 1577, having been twenty years employed in a miſſion, for which he was in no reſpect properly qualified. Gen. Biog.

OVIEDO, GONZALO FERNANDEZ DE, one of the earlieſt hiſtorians of the new world, was born at Madrid in 1478. He ſpent his youth about the court, and became page to Ferdinand king of Arragon, and Iſabella queen of Caſtile. He accompanied Columbus on his firſt voyage to Hiſpaniola, where he reſided many years, and wrote the "Hiſtoria General de las Indias," in fifty books. Twenty-one of theſe were printed at Seville in 1535, and at Salamanca in 1547. A ſummary of this work, which Oviedo drew up for the emperor Charles V., is inſerted in Barcia's collection of the "Hiſtoriadores Primitivos de las Indias Occidentales." This ſummary contains the moſt deciſive paſſage concerning the importation of "Syphillis" from America, that is any where to be found. He wrote two tracts concerning the "Palo de Guayacan," and the "Palo Santo," tranſlations of which are in the firſt volumes of his collection "Scriptorum de Morbo Gallico." The office of chronicler was given to him by Charles V. when he was in the ſeventieth year of his age. He left behind him many unpubliſhed works, beſides the ſequel of his great hiſtory. Moreri. Gen. Biog.

OVIEDO, *Ovietum*, in *Geography*, an ancient town of Spain, the only city and the capital of the Aſturia of its name. It is ſituated on a plain, rather elevated, at the confluence of the two little rivers Ovia or Ove, and Nora, the former of which runs into the Nora, and this into the Nalon, the firſt running to the N., and the ſecond to the S. of Oviedo. Some, without ſufficient authority, have made Oviedo the "Lucus Aſturum;" others have deduced its name from the Ovia, after Froila, the grandſon of Pelagius, had built it in 757; and according to others again, it was ſo conſiderable in the time of Pelagius, that after his firſt acceſſion he made it the chief place of his ſtates, and transferred to it the epiſcopal ſee of a neighbouring town called "Emerita." However this be, Oviedo, in the ninth century, was honoured throughout Chriſtendom with the ſingular title of "the city of biſhops," becauſe a number of them, exiled and perſecuted by the Saracens, took refuge in this place. In 901 a council was held here, and while it was convened, the biſhopric was elevated into an archbiſhoric by the pope, which dignity was afterwards transferred to the church of St. Jago de Compoſtella: and Oviedo again became a biſhopric: the revenue of it is eſtimated at 1250*l.*

Oviedo contains an epiſcopal palace, a cathedral, a collegiate chapter, three pariſhes, three convents of monks, three of nuns, three colleges, three hoſptials, an univerſity founded in 1580, a drawing ſchool, a royal audience, an alcade mayor, a common adminiſtration, &c. Its population is eſtimated at about 6400 inhabitants. The ſtreets are tolerably ſtraight, regular, and well paved; the principal ſquare is handſome and large, and almoſt all the ſtreets open into it, and the market is held there. The public edifices are a Gothic cathedral, ſaid to be built by Froila I. in 760, and containing a rich treaſury of valuable vaſes, relics and ornaments, and the bones of 14 kings and queens; the beautiful church of San Salvador, built by a prince named Sito, who flouriſhed in 774, and enriched by a great number of relics; the univerſity, which is conſidered one of the handſomeſt ornaments of the town; and the aqueduct of forty arcades. Oviedo has little commerce: it has two tan-yards, a manufactory of hats, one of horn-combs and bone buttons, and a grand magazine of arms for the army; 47 miles N. of Leon. N. lat. 43° 19′. W. long. 5° 57′.

OVILIA, or SEPTA, in *Ancient Rome*, a place in the Campus Martius, at firſt railed in like a ſheep's pen; whence its name.

Afterwards it was mounted with marble, and beautified with walks and galleries; as alſo with a tribunal, or ſeat of juſtice.

Within this precinct, or incloſure, the people were called to give their ſuffrages for the election of magiſtrates.

The aſcent into the ovilia was not by ſtairs, but by pontes; a ſort of bridges made for the time; every curia, tribe, and century, as the aſſembly was centuriate or tribute, &c. having its proper bridge.

Whence the proverb, *de ponte dejiciendus*, where a perſon is to be debarred from giving his vote. See COMITIA.

OUINEASKE, or SHELBURNE *Bay*, in *Geography*, a bay on the E. ſide of lake Champlain, which ſets up ſoutherly, through the town of Burlington, in Vermont, into the northern part of Shelburne.

OUINICHTAGAN, a lake of Lower Canada; 138 miles N. of Quebec. N. lat. 50°. W. long. 70° 56′.

OVIPAROUS, in *Natural Hiſtory*, a term applied to ſuch animals as produce their young *ab ovo*, *from eggs*; as birds, inſects, &c.

The oviparous kind ſtand in oppoſition to thoſe which bring forth their young alive, called viviparous animals, as man, quadrupeds, &c.

Oviparous animals may be defined to be ſuch as conceive eggs, which they afterwards bring forth, and from which, by the incubation of the parent, or ſome other principle of warmth and fermentation, at length ariſe animals; which after they have ſpent the moiſture or humour they were ſurrounded withal, and are grown to a ſufficient bulk, firmneſs, and ſtrength, break their ſhell, and come forth.

The oviparous kind, beſide birds, include divers ſpecies of animals; as ſerpents, lizards, tortoiſes, crabs, lobſters, frogs, &c. See EGG.

The diſtinction between oviparous and viviparous creatures, ſeems, in the inſect world, to be much leſs fixed and determinate than is ſuppoſed. It is evident, that ſome flies, which are naturally oviparous, if they are kept from the finding a proper nidus for their eggs, be it meat, or any thing elſe, will retain them ſo long beyond their due time of excluſion, that they will hatch into worms in the body of the parent, and be afterwards depoſited alive in fleſh, or in the manner of the young of the viviparous inſects. Bartholine gives an account, in his Medical Obſervations, of a hen, which, inſtead of eggs, brought forth no leſs than five living chickens; but ſhe died of it.

OVIS, the Sheep, in *Zoology*, a genus of the claſs and order Mammalia Pecora. The generic character is; horns hollow, wrinkled, turned backwards and outwards into a circular or ſpiral form. It has eight lower fore-teeth, and is without tuſks. The animals of this genus are gentle, harmleſs, and uſeful; they ſupply food and raiment, and prefer open plains; they are not very active, and fight by butting each other with the head reclined; they threaten by ſtamping the ground with their feet; they drink little; the females are gravid five months, bring one or two, rarely three, young at a time. According to the Linnæan ſyſtem there are four ſpecies, but Dr. Shaw includes the whole genus in three ſpecies, making the *ſtrepſiceros*, or Cretan ſheep, a mere variety of O. aries. We ſhall abide by the Linnæan arrangement.

Species.

ARIES; Common ſheep. Horns compreſſed and lunate. Of this ſpecies there are 13 varieties.

1. The hornleſs ſheep, of which the tail and ſcrotum hang as low as the knees; breeds of this kind of ſheep are raiſed in many counties of England, and ſome other parts of Europe.

2. Black-faced ſheep; this is horned; the tail is ſhort; the wool is ſhort and coarſe.

3. Spaniſh ſheep that has ſpiral horns, lengthened outwards; the wool is fine and plentiful. The principal diſtinction of the Spaniſh ſheep is the fineneſs of the fleece, and the horizontally extended ſpire of the horns.

4. Many-horned ſheep; this has more than two horns; it occurs in the northern parts of Europe more frequently than in other regions, and is ſaid to be the moſt common in Iceland. The horns are either three, or four, or five, in number; ſometimes placed with the greateſt regularity, and ſometimes differing in proportion and ſituation. A four-horned variety, with very long hairs hanging from the breaſt, is alſo found in ſome parts of Europe; the two largeſt horns are ſtraight, and nearly upright on the top of the forehead, while the ſmaller pair are ſeated on each ſide the head, and turn downwards.

5. African ſheep. Hair inſtead of wool, ſhort.

6. Guinea ſheep. Ears pendulous; dewlaps lax, hairy; hind part of the head prominent. This, which is ſometimes termed the Cape ſheep, and which is erroneouſly mentioned in Buffon's Natural Hiſtory as of Indian extraction, is ſuppoſed to be moſt frequent in Guinea, and is diſtinguiſhed from others by its remarkably meagre appearance, length of neck and limbs, pendant ears, and long arched or curved viſage. It is covered with hair rather than wool, and has a pair of pendent hairy wattles beneath the neck, as in goats. The horns are ſmall, and the tail long and lank.

7. Broad-tailed ſheep. This is diſtinguiſhed by a long and very broad tail. It is found in Syria, Barbary, and Ethiopia. Alſo in Tartary, Tibet, &c. Its general appearance, as to the other parts of the body, ſcarcely differs from that of European ſheep, and in Tibet it is remarkable for the exquiſite fineneſs of its wool. The tails of theſe ſheep are ſaid to grow ſo large as to weigh from fifteen to fifty pounds, and in order to enable the animal to graze with convenience, the ſhepherds are often obliged to put a board, furniſhed with ſmall wheels, under the tail. This part of the ſheep, as an article of food, is reckoned a great delicacy.

8. Fat-rumped ſheep. Ears large, pendulous; large fatty cuſhions on the hips, and without a tail; or if there be a tail it is ſo enveloped with fat as to be ſcarcely viſible, the parts on each ſide ſwelling out into a pair of naked hemiſpheres, of ſuch a ſize as ſometimes to weigh nearly forty pounds. The ſheep of this variety are found in many of the Tartarian deſerts from the Wolga to the Irtis and the Altaic chain of mountains.

9. Bucharian ſheep. Ears large, pendulous; cuſhions on the hips leſs; the tail is long and flat.

10. Long-tailed ſheep. The tail is very long and woolly.

11. Cape ſheep. Ears large, pendulous; tail large and broad.

12. Bearded ſheep. Beard long, divided, hanging from the lower parts of the cheeks and upper jaw.

13. Morvant. Beard long, on the fore-part of the breaſt; neck with a ſhort mane.

Such are the ſeveral varieties as deſcribed by Gmelin and others; who obſerve that this animal, in its ſtate of complete domeſtication, appears as ſtupid as it is harmleſs; it is characteriſed by Buffon as one of the moſt timid, imbecile, and contemptible of quadrupeds. When ſheep, however, have an extenſive range of paſture, and are left, in a conſiderable degree, to depend on themſelves for food and protection, they exhibit a more decided character. A ram has been ſeen in theſe circumſtances to attack and beat off a large and formidable dog, and even a bull has been felled by a ſtroke received between his eyes as he was lowering his head to receive his adverſary on the horns and toſs him in the air. Sheep diſplay conſiderable ſagacity in the ſelection of their food, and, in the approach of ſtorms, they perceive the indications with accurate preciſion, and retire for ſhelter always to the ſpot which is beſt able to afford it. The ſheep is more ſubject to diſorders than any of the domeſticated animals; giddineſs, conſumption, ſcab, dropſy, and worms frequently ſeizing upon and deſtroying it. Of all diſorders the moſt fatal is owing to vaſt numbers of worms of the genus *faſciola* (which ſee), which are found in the liver and gall-bladder. They are of a flat form, of an oval ſhape, with ſlightly pointed extremities, and bear a general reſemblance to the ſeeds of a gourd. The fly is another formidable enemy, and is often fatal in the courſe of twenty-four

hours, breeding within the ſkull of the animal. To extricate the ſheep from this danger, the French ſhepherds apply the *trephine* without the ſmalleſt heſitation, and with the greateſt diſpatch and ſucceſs.

AMMON; Siberian ſheep. Horns arched, ſemi-circular, above wrinkled, flattiſh beneath, dewlaps lax, hairy. A variety of this ſpecies has its body brown tinged with tawny; a white mark on each ſide pointing to the belly. It inhabits in flocks the rocky dry deſerts of Aſia, Barbary, and Corſica; it is the ſize of a ſmall deer; active, ſwift, wild; the fat and fleſh are delicious. In ſummer the colour is browniſh-aſh mixed with grey; beneath whitiſh-grey; the tail is ſhort, white and browniſh at the tip; the hair is long in the winter, and is ſhed in the ſpring; the ears are erect, acute; the hind-feet are longer than the fore. The favourite regions of theſe wild ſheep are Siberia, Kamtſchatka, and the Kurile iſlands. They are ſocial animals, and feed together in ſmall flocks. They are the moſt uſeful animals that the Kamtſchadales poſſeſs.

PUDU. Horns round, ſmooth, divergent. It inhabits the Cordilleras in South America, is gentle, deſcends in the winter into the vallies; ſize of a half-grown kid, and reſembles a goat, but the horns are turned round outwards; it has no beard, the female is without horns, the colour is duſky. The animals of this ſpecies feed together in flocks; in the mildeſt months they frequent the ſummits of the mountains, but retire from the ſeverity of winter into the vallies, where they are eaſily taken, and when taken, of whatever age, it is not difficult to domeſticate them.

STREPSICEROS; Cretan ſheep. Horns erect, carinate, ſpirally twiſted. It is found principally in the iſland of Crete, and is kept in ſeveral parts of Europe for the ſingularity of its appearance; the horns being very large, long, and twiſted like a ſcrew; thoſe of the male are upright; thoſe of the female at right angles to the head.

OUISCONSING, in *Geography*. See OOISCONSIN. This river has a communication with Fox river, which paſſing through Winnebago lake, enters Puan bay in lake Michigan. On this river and its branches reſide the Indians of its name, furniſhing 300 warriors.

OUISTISI, in *Zoology*. See SIMIA *Iacchus*.

OUITANOU, or OUIATANON, in *Geography*, a town and fort of North America, in the Indiana territory, on the W. ſide of the Wabaſh. N. lat. 40° 38′. W. long. 87° 58′. Thus far the Wabaſh is navigable, 412 miles from its mouth, for batteaux drawing three feet water. A ſilver mine has been diſcovered here. The neighbouring Indians are the Kickapoos, Muſquitons, Pyankiſhaws, and a principal part of the Ouiatanons. All theſe tribes, collectively, could, about 30 years ago, furniſh 1000 warriors.

OUJULDINGA, a town of Bengal; 25 miles N.E. of Kiſhenagur.

OUJULINKA, a town of Thibet, near lake Jamdro; 42 miles E.S.E. of Kiang-ſee.

OUKAKEE, a lake of Canada; N. lat. 50° 20′. W. long. 86° 30′.

OUKERCK, a town of Holland; 7 miles. S. of Naarden.

OUKE-SIMA, an iſland in the Chineſe ſea, near the coaſt of Tonquin; about 30 miles in circumference. N. lat. 18° 44′. E. long. 105° 42′.

OUKE-TANACSA, a town of Thibet; 90 miles E. of Laſſa.

OULAIS, a town of Sweden, in the government of Ulea; 25 miles S.S.E. of Braheſtadt.

OULAN-HOTUN, a town of Chineſe Tartary, in the territory of the Monguls; 120 miles N. of Peking.

OULAN-TABALAN, a town of Thibet; 58 miles S. of Cha-tcheou.

OULART, a ſmall poſt-town of Ireland, in the county of Wexford; 57 miles S. from Dublin and 10 N. from Wexford.

OULBARAYA, a town of Bengal; 48 miles E.S.E. of Burdwan.

OULCHY *le Chateau*, a town of France, in the department of the Aiſne, and chief place of a canton, in the diſtrict of Soiſſons; 10 miles S. of Soiſſons. The place contains 307, and the canton 7790 inhabitants, on a territory of 260 kiliometres, in 31 communes.

OULLER, or TAL, the name of a lake in Hindooſtan, which lies near Sirinagur, and receives the river Behut. This lake is ſaid to be of great extent, no leſs than 53 Britiſh miles in circuit, or perhaps 16 or 17 acroſs; according to which ſtatement it may reach to the frontiers of Little Thibet. The courſe of the Behut is to the N.W. from Sirinagur to the lake; but the length of its courſe in this direction is not aſcertained, any more than the length and direction of its courſe from the lake to its entry between the mountains at Barchmooleh. It may, however, be inferred, that the courſe of the Behut, after its efflux from the lake, is ſhort, and towards the S.W. quarter; by which, Barchmooleh will take a W. by N., or W.N.W. poſition, in reſpect of Sirinagur.

OULNEY. See OLNEY.

OULSTEEN, an iſland near the coaſt of Norway, triangular in its form, and 24 miles in circumference; 120 miles N. of Bergen.

OULUA, a town of Hindooſtan, in Bahar; 20 miles S.S E. of Bettiah.

OULUSTON, a lake of Chineſe Tartary, in the country of the Monguls. N. lat. 43° 25′. E. long. 114° 42′.

OULX, a town of France, in the department of the Po, late in Piedmont, ſituated in a valley, which derives from it its name; taken by the French in May 1794; 5 miles N. of Sezanne.

OUMA, a river of Africa, in Congo, which runs into the Bokian; 15 miles S. of Pango.

OUMARY, a town of Hindooſtan, in Goondwana; 16 miles S of Nagpour.

OUMIEN, a name given by the Chineſe to a peculiar ſort of porcelain, of which they are very fond. It is black, ornamented with gold. They ſometimes alſo call the blue and gold, which is made in the ſame manner, by the ſame name. They colour it with three parts of the azure, and ſeven parts of oil of ſtone, and lay on the gold afterwards. If they would have it blueiſh, they add leſs of the azure, and ſome ceruſs white.

OU-MONG, in *Geography*, a town of the firſt rank in China, in Se-tchuen. N. lat. 27° 20′. E. long. 103° 29′.

OUNCE, UNCIA, a little weight, the ſixteenth part of a pound avoirdupois; and the twelfth of a pound troy.

The word is derived from the Latin, *uncia*, the twelfth part of any whole, called *as*; particularly in geometrical meaſures, an inch, or the twelfth part of a foot.

The ounce *avoirdupois* is divided into ſixteen drachms.

The ounce *troy* into twenty penny-weights, and the penny-weight into twenty-four grains. See WEIGHT.

The ounce, *once*, makes the eighth part of a French mark, and is divided into three groſs or drachms: the drachm into three penny-weights or ſcruples; and the ſcruple into twenty-four grains; each grain being computed to weigh a grain of wheat.

All precious merchandizes, as gold, ſilver, ſilk, &c. are ſold by he ounce.

Ounce *Pearls*, are thoſe too ſmall to be ſold by tale; uſually called *ſeeds of pearl*, or *ſeed-pearls*.

Ounce *Cottons*, brought from Damaſcus, are of a kind and quality ſuperior to any other cotton.

Ounce, in *Zoology*. See Felis.

OUNDLE, in *Geography*, a market-town and pariſh, in the hundred of Polebrook, and county of Northampton, England, is ſituated on the north bank of the river Nen, which, making a horſe-ſhoe bend in its courſe here, almoſt environs the town. Camden, and the author of "Magna Britannia," aſſert that its proper name is Avondale, as ſtanding in the vale of Avon, the original appellation of the Nen. But this opinion ſeems extremely doubtful, as we find this place mentioned in the Domeſday-book, under the deſignation of Undele. The market-day in Oundle is Saturday, and there are four fairs annually. Here is an excellent free grammar-ſchool, founded by ſir William Laxton, a native of the town, and who was lord-mayor of London in 1544. The ſame beneficent perſon likewiſe erected and endowed the alms'-houſe, and placed both it and the ſchool under the patronage of the Grocers' company of London, of which he was a member. The charity-ſchool, eſtabliſhed in 1620, owed its origin to the munificence of Nicholas Latham, who was for more than fifty years rector of Barnwell St. Andrew's. This perſon alſo founded a guild, or hoſpital here for the reception of ſixteen aged women, who have a weekly allowance for their ſupport.

The church belonging to this town is a ſpacious edifice, conſiſting of a nave, north and ſouth aiſles, tranſept and chancel, with a ſquare tower, ſurmounted by an hexagonal, crocketted ſpire. The tower diſplays a ſeries of five ſtories, and is terminated at each angle by a ſmall octagonal turret. Over the river here are two large bridges, one on the road towards Thrapſton, and the other on that leading to Yaxley, in Huntingdonſhire. The former, called North-bridge, is generally much admired, not only on account of the number and forms of its arches, but alſo for its cauſeway, which is formed on an arcade, and ſecures a paſſage to and from the place during the time of floods. Peter Hauſted, author of the "Rival Friends," "Senile Odium," &c.; and Dr. John Newton, a celebrated divine and mathematician, were natives of this town.

About three miles to the ſouth-eaſt of Oundle, the Roman road called the Via-Devana croſſes the country in an oblique direction from ſouth-eaſt to north-weſt. Adjoining to this road is the pariſh and village of Aldwinckle-All-Saints, diſtinguiſhed as the birth-place of the poet Dryden, one of the moſt original and energetic writers of his age. Aldwinckle-St. Peter's, to the weſt of this pariſh, is likewiſe noted as the birth-place of Dr. Thomas Fuller, author of a "Church Hiſtory," "A Hiſtory of the Worthies of England," and various other works. (See Fuller.) At Barnwell St. Andrew ſtand the ruins of a caſtle, erected by Reginald le Moine, and deſcribed by Leland under the title of "Berengarius Moynes Caſtel." It was long the baronial reſidence of the Montecute and Montague families, but has been for many years uninhabitable. It ſtill forms, however, a very noble and curious ſpecimen of ancient architecture, much of the original ſtructure having ſurvived the attacks of time and of alteration. The preſent remains conſiſt of four round maſſy baſtion towers, one ſtanding at each angle of a quadrangular court, which is incloſed by a wall three feet in thickneſs. Three of theſe connecting curtains are nearly entire, but that on the weſtern ſide is conſiderably dilapidated. The grand gateway, at the ſouth-eaſt front, ſtill remains, and is flanked by ſimilar circular baſtion towers of ſmaller dimenſions.

Cliff-Regis, or King's-Cliff, ſituated north-weſt from Oundle, is traditionally ſaid to have derived its name from the circumſtance of king John having had a hunting-ſeat here. It was formerly a market-town, but this privilege has been long diſcontinued. The Rev. William Law, a celebrated polemical and non-juring divine, was born at this place in 1686. He is chiefly diſtinguiſhed for his zealous vindication of the doctrine of the euchariſt againſt the ſentiments maintained by biſhop Hoadly, in the Bangorian controverſy.

The village of Fotheringay, which lies to the eaſt of King's-Cliff, and rather nearer to Oundle, is a place conſpicuous on the page of Engliſh hiſtory. Here was anciently a caſtle, probably firſt erected by Simon St. Liz, or Senliz, ſecond earl of Northampton, in the time of the Conqueror. It was afterwards entirely rebuilt, however, in the reign of Edward III., by Edmund Langley, duke of York, and paſſed by marriage from that family into the poſſeſſion of the Scottiſh kings, and in the 14th year of the reign of king John, David of Scotland was ſummoned to ſurrender it to the crown of England. William de Fortibus, earl of Albemarle and Holderneſſe, took it by ſurpriſe when it was held by Ranulph, earl of Cheſter, and having placed a garriſon in it, ravaged the adjacent country. It was ſoon again, however, yielded to the crown, and conſtituted for ſome time the reſidence of king Edward IV., and here Alexander, king of Scotland, had an audience of that monarch, and promiſed to do fealty and homage to him for his poſſeſſions in England. Henry VIII. ſettled this honour in dower on queen Catharine of Arragon, whom he ſo flagriouſly divorced. But what renders it more particularly a ſubject of hiſtorical intereſt, is its connection with the fate of the unfortunate Mary, queen of Scots, who was tried, condemned, and executed here, to the indelible blemiſh of the otherwiſe illuſtrious reign of her rival Elizabeth. Nothing now remains of this once noble pile but the ſcite, the whole having been razed to the ground by the order of king James, immediately after his acceſſion to the Engliſh throne.

Fotheringay village was formerly much more extenſive and important than at preſent. It was indeed a conſiderable town, and had a weekly market, and three annual fairs. The grammar-ſchool, which is ſtill ſupported, was erected and endowed by queen Elizabeth. The church anciently belonged to a college for ſecular canons, founded by Edward, duke of York, in the year 1412, whoſe revenues at the diſſolution amounted to 489*l.* 15*s.* 9*d.* It contains ſeveral monuments in honour of the dukes of York. Brydges's Hiſtory and Antiquities of Northamptonſhire, 2 vols. folio. Beauties of England and Wales, vol. xi., by John Britton, F.S.A.

OUNIAH, a town of Aſiatic Turkey, in the government of Sivas, on the Black ſea; 80 miles N. of Sivas.

OVO, a ſmall iſland in the Mediterranean. N. lat. 35° 39′. E. long. 25° 27′.

OVOCA, a river of Ireland, in the county of Wicklow, which runs into St. George's channel, a little below the town of Arklow, which is ſituated on it. It paſſes through a very intereſting country, both as to natural beauties and mineralogical productions. In one of its tributary ſtreams were found the pieces of gold which have excited ſo much attention.

OVOLO, Ovum, in *Architecture*, a round moulding, whoſe profile or ſweep in the Ionic and Compoſite capitals, is uſually a quadrant of a circle; whence it is alſo popularly called the *quarter-round*

It is uſually enriched with ſculptures among the ancients,

in form of chefnut fhells; whence Vitruvius, and others of the ancients, call it *echinus*, chefnut-fhell.

Among us, it is ufually cut with the repreſentation of eggs and anchors, or arrows' heads, placed alternately; whence its Italian name *ovolo*; Latin, *ovum*; and French, *œuf*; q. d. *egg*.

OUPLE, in *Geography*, a town of Hindooſtan, in Dowlatabad; 10 miles E. of Perinda.

OUR, in *Ichthyology*, a variety of the MUGIL *ebulé*.

OUR *Lady*. See NOTRE DAME.

OUR *Lady of the Thiſtle*. See THISTLE.

OURA, in *Geography*, a town of Portugal, in the province of Tras los Montes; 9 miles S. of Chaves.

OUR\N, or URAN SOANGUS, the name of an imaginary ſect of magicians in the iſland Gromboccanore, in the Eaſt Indies.

The word implies *men-devils*: theſe people were ridiculouſly ſuppoſed to have had the art of rendering themſelves inviſible, and paſſing where they pleaſed, and, by theſe means, doing infinite miſchief; for which reaſon the people hate and fear them exceedingly, and always kill them on the ſpot, when they can take them.

OURDA, in *Geography*, a town of Bengal; 72 miles N. of Dacca.

OUREM, a town of Portugal, in Eſtramadura, ſeated on a mountain, containing 1800 inhabitants; 12 miles W. of Thomar.

OUREOS, a ſmall iſland in the gulf of Engia; 14 miles N W. of Engia.

OURFA, ROIHA, or *Rouah*, a town of Aſiatic Turkey, in the province of Diarbekir, anciently called "Edeſſa," which ſee; watered by a canal from the Euphrates. Many perſons, particularly among the learned Jews, have ſuppoſed it to have been the Ur of the Chaldees. The Greeks gave it the name of Edeſſa; and in honour of Antiochus, it was called Antiochia, which was diſtinguiſhed from others of the ſame name by the famous fountain Callirrhoe, and denominated Antiochia ad Callirrhoem.

Ourfa is built upon two hills, and in the valley between them, at the S.W. corner of a fine plain, rendered more beautiful by the rocky, mountainous parts that ſurround it: it is about three miles in circuit, encompaſſed by ancient walls, and defended by ſquare towers. On the north ſide is a deep foſſe, and the caſtle ſtands on a hill to the ſouth. Although the town is not well laid out, parts of it are well built. Its chief beauty conſiſts in ſome fine ſprings, that riſe between the two hills, and even in the walls of the city. The aſcent to the caſtle is very ſteep, and on three ſides of it is a deep foſſe: it is about half a mile in circumference, and has two Corinthian pillars, the capitals of which are admired; the columns conſiſt of 26 ſtones, each about one foot ſix inches thick. They are probably the remains of a portico belonging to ſome large temple. According to tradition, the throne of Nimrod ſtood on theſe pillars; but it is certain that Timur Bec erected ſome trophies on them. Ourfa is the reſidence of a pacha, who commands not only the greateſt part, if not the whole, of Macedonia, but a conſiderable tract of country to the weſt of it as far as Antab. This place carries on a great trade, as it is the great thoroughfare into Perſia. They prepare Turkey leather here, eſpecially that of the yellow kind, for which they were formerly famous. The Armenian Chriſtians, of whom there is a conſiderable number, have two churches, one in the city and another near it, in the latter of which they ſhew the tomb of a great ſaint, whom they call Ibrahim, and who was probably Ephraim Syrus, formerly deacon of Edeſſa. The ſurrounding country is fertile in corn and fruit. This town was firſt taken by the Saracens in 1087, retaken by the Chriſtians in 1097, and ſeized in 1142 by the Turks, who have ever ſince retained poſſeſſion of it; 80 miles S.W. of Diarbekir. N. lat. 36° 50'. E. long. 38° 25'.

OURGOOR, a town of Hindooſtan, in Golconda; 30 miles N.N.W. of Rachore.

OURICO, in *Zoology*. See HYSTRIX *Prehenſilis*.

OURIGUI, in *Geography*, a town of Hindooſtan, in Dowlatabad; 15 miles S.S.E. of Kondur.

OURIQUE, a town of Portugal, in Alentejo, containing about 2000 inhabitants; 24 miles S.W. of Beja. N. lat. 37° 39'. W. long. 8° 9'.

OURISIA, in *Botany*, a name of which we find no explanation. It was contrived by Commerſon; poſſibly from ὄρος, ὄρεος, *a mountain*, in alluſion to the natural ſtation of the plant. Juſſ. 100. Brown. Prodr. Nov. Holl. v 1. 438. Claſs and order, *Didynamia Angioſpermia* Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ. *Scrophularinæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, in five deep, ſomewhat unequal ſegments, permanent. *Cor.* of one petal; tube funnel-ſhaped, aſcending, longer than the calyx; limb in five, obtuſe, nearly equal lobes. *Stam.* Filaments four, inſerted into the bottom of the tube, curved cloſely along its upper ſide, two of them rather the longeſt; anthers incumbent, within the tube; ſome deſcribe the rudiment of a fifth ſtamen. *Piſt.* Germen ſuperior, two lobed; ſtyle the length and poſition of the ſtamens; ſtigma of two obtuſe lobes. *Peric.* Capſule two-lobed, of two cells, and two valves, the partitions from the centre of the valves. *Seeds* numerous, with a lax tunic-like ſkin.

Eſſ. Ch. Calyx deeply five-cleft, rather unequal. Corolla funnel-ſhaped; limb five-cleft, nearly equal, obtuſe. Stigma two-lobed. Capſule of two cells, and two valves; the partitions from the centre of each valve. Seeds with a lax tunic-like ſkin.

1. O. *ruelloides*. (Chelone ruelloides; Linn. Suppl. 279. Willd. Sp. Pl. v. 3. 226.)—Leaves roundiſh-ovate, unequally crenate. Flower-ſtalks axillary, oppoſite.—Native of Terra del Fuego, in the clefts of rocks. *Root* perennial, creeping, with woolly fibres. *Stems* procumbent, ſhort, ſmooth. *Leaves* on long erect ſtalks, roundiſh-ovate, about two inches long, nearly ſmooth, with one central rib, and two pair of lateral ones, their margin unequally and rather bluntly crenate; the under ſide paleſt. Flowering *branches* decumbent, hardly a ſpan long, ſmooth, bearing two or three pair of rounded notched leafy *bracteas*. *Flowers* purple, on long, ſmooth, axillary, ſolitary, oppoſite, naked, ſimple *ſtalks*, from the two uppermoſt pair of *bracteas*. *Calyx* fringed. See CHELONE, ſp. 3. erroneouſly printed *melloides*.

2. O. *integrifolia*. Brown. n. 1.—Leaves nearly ovate, entire. Flower-ſtalk terminal, moſtly ſolitary. Gathered by Mr. Brown in Van Diemen's land. A ſmooth creeping plant, with a *calyx* more equally and deeply divided than the firſt ſpecies, as well as a ſhorter *corolla*, and a different aſpect, ſo that its diſcoverer was partly inclined to think it generically diſtinct. We have ſeen no ſpecimen of this laſt.

OURISSIA, in *Ornithology*, a ſpecies of the *Trochilus*; which ſee.

OURO, in *Geography*, a river of Africa, which runs into the Atlantic, N. lat. 23° 30'.—Alſo, a river of Africa, which runs into the Indian ſea, S. lat. 24° 25'.

OUROE, a ſmall iſland of Denmark, near the coaſt of Zealand, in the Iſefiord gulf; 4 miles N.E. of Holbeck. N. lat. 55° 46' E. long. 11° 50'.

OUROLOGY, in *Medicine*, is the doctrine of diſeaſes, as judged of by the appearances of the *urine*.

The changes in the ſenſible qualities of the urine, under different

different circumſtances of diſeaſe, are conſiderable, and the ancients deduced many pathological inferences from theſe changes, and wrote ample treatiſes in explanation of their doctrines. Much of their ſuppoſed knowledge on the ſubject was, however, purely hypothetical, and altogether unworthy of ſerious attention. Although, doubtleſs, ſome indications are to be obtained from the appearances of the urine, both in acute and chronic complaints, yet theſe are much more limited than was formerly believed; and thoſe who pretend to aſcertain the nature of diſeaſes, by inſpecting the urine of the patient alone, are, therefore, impoſtors of the loweſt claſs; and it is truly diſcreditable to the general information of the age, that the Meyerſbachs and Van Butchels ſtill live upon the credulity of a Britiſh people.

The medical indications, as well as the chemical properties, of this excretion, will be treated of under the proper head. In the mean time, we may obſerve, that Dr. Blackall, a phyſician of Exeter, has recently given an importance to *uroſcopy*, which it never before poſſeſſed, by ſhewing that, in many caſes of dropſy, and other chronic diſeaſes, the urine contains much of the coagulable part of the blood, and thence deducing ſome important practical indications. See URINE.

OUROVANG, in *Ornithology*. See TURDUS *Urovang*.

OURRED, in *Geography*, a high hill of the county of Galway, Ireland, in the weſtern diſtrict, at the bottom of which is a lake of the ſame name.

OURRY'S ISLAND, or *New Alderney*, an iſland in the South Pacific ocean, diſcovered by Capt. Carteret, in Auguſt 1767, being one of the cluſter called Queen Charlotte's iſlands, about ten miles long and three broad. S. lat. 11° 10'. E. long. 165° 19'.

OURS, in *Zoology*. See URSUS.

OURSE, in *Geography*, a river of France, which runs into the Seine, at Bar ſur Seine.

OURTE, or OURTHE, one of the 13 departments of the region of France, called the Reunited country, formed of part of Liege and of Limbourg, and deriving its name from the river Ourte, or Ourthe, which riſes from two ſprings, one near St. Hubert, the other near the town of Ourte, both which unite near La Roche, and run into the Meuſe at Liege. This department is 42 French leagues long, and 12 broad, contains 4002½ kiliometres, or 213 ſquare leagues, and 313,876 inhabitants, and is ſituated N.E. of Sambre and Meuſe, in N. lat. 50° 35'. It is divided into three circles or diſtricts, 30 cantons, and 383 communes. The circles are Liege, including 151,975, Malmedy, 100,565, and Huy, 61,336 inhabitants. According to Haſſenfratz, it comprehends 5 circles, 36 cantons, and 310,444 inhabitants. Its contributions amounted, in the 11th year of the French era, to 2,424,974 francs, and its expences to 295,573 fr. 39 cents. Its capital is Liege. The firſt of the circles abounds in mines of iron, coal, and alum; in the ſecond are Spa waters; and in the third are mines of iron, alum, ſulphur, coal, &c.

OURTHE, or OURT, a town of France, in the department of the Foreſts, 4 miles N. of Luxemburg.

OURTON-POULAC, a town of Thibet; 15 miles S.W. of Yolotou-Hotun.

OURTS, in *Agriculture*, a provincial term applied to the leavings of fodder made by cattle. Sometimes written *orts*.

OURUCZE, in *Geography*, a town of Poland, in Volhynia; 68 miles N.N.E of Zytomiers.

OURVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Yvetot; 9 miles W. of Fécamp. The place contains 1257, and the canton 9553 inhabitants, on a territory of 117½ kiliometres, in 19 communes.

OUSBY, a town of Sweden, in the province of Schonen; 23 miles N. of Chriſtianſtadt.

OUSCOTTA, a town and fortreſs of Hindooſtan, in Myſore, taken by earl Cornwallis in April 1791; 15 miles N.E. of Bangalore.—Alſo, a town of Hindooſtan, in the circar of Sanore; 25 miles N. of Sanore.

OUSE, or *Grand River*, a river of Canada, which riſes in the country belonging to the Chippewa and Miſſaſſaga Indians, and running ſoutherly through the weſt riding of the county of York, croſſes Dundas ſtreet, and paſſing between the counties of Lincoln and Norfolk, diſcharges itſelf into lake Erie, about half-way between the Foreland and fort Erie. N. lat. 42° 50'. W. long. 79° 30'. About 40 miles up this river is the Mohawk village. The Senecas, Onondagoes, Cayugas, Augagas, Delawares, and Miſſaſſagas, have alſo villages on different parts of this river.

OUSE, a large river of England, which riſes in two branches not far from Brackley and Towceſter, on the borders of Northamptonſhire and Oxfordſhire, whence it flows eaſtward, through Buckinghamſhire, by Newport-Pagnell and Olney, into Bedfordſhire. After flowing ſeveral miles in the ſame direction, it makes a rapid ſweep to the ſouth, deſcending as far as Bedford, at which place it again bends to the north-eaſt, paſſing through the centre of the fens of Cambridgeſhire, where it is joined by the Cam, the Leſſer Ouſe, and the Larke, all of which are conſiderable ſtreams. It afterwards enters Norfolk, and traverſes the weſtern diviſion of that county, till it falls into The Waſh, a gulf of the ſea formed by the projecting coaſts of Norfolk and Lincolnſhire. A general Account of all the Rivers of Note in Great Britain, &c.; by Henry Skrine, eſq. L.L.B. 8vo. Lond. 1801. Beauties of England and Wales, vol. xi. Northamptonſhire.

OUSE, a large river in Yorkſhire, England, is formed by the junction of the Ure and the Swale, two very conſiderable ſtreams, which take their riſe in the northern moors of the county. The courſe of this river is nearly ſouth-eaſt, by Nun-Monkton, where its waters are increaſed by thoſe of the Nid, to the city of York; after paſſing which, it flows almoſt directly ſouth to Cawood Near this place it is joined by the Wharfe, which has its ſource at the foot of the Craven-Hills, and changing its direction again to the ſouth-eaſt, runs paſt the town of Selby. About five miles below that town it receives the Derwent, and two miles ſtill lower down, the Aire, the ſecond moſt conſiderable river of Yorkſhire. Thus augmented, the Ouſe becomes as wide as the Thames at London, and after making a circuit to the ſouth near Swinefleet, takes a north-eaſterly direction to its confluence with the Trent from Lincolnſhire These rivers united conſtitute the Humber, which is the moſt important eſtuary in the north of England. See HUMBER. A general Account of all the Rivers of Note in Great Britain, &c. by Henry Skrine, eſq. L.L.B. 8vo. 1801.

OUSEEL, PHILIP, in *Biography*, a learned German, who flouriſhed in the eighteenth century, was born at Dantzic in the year 1671. He became miniſter of the German church at Leyden, and was afterwards profeſſor of divinity at Frankfort on the Oder. He died in 1724, at the age of fifty-three. His moſt important works are, "Introductio in accentuationem Hebræorum Metricam;" "Introductio in accentuationem Hebræorum Proſaicam;" "De Lepra;" and ſome treatiſes on the ten commandments.

OUSERAU, in *Geography*, a town of Hindooſtan, in Bahar; 25 miles W.N.W. of Rotaſgur.

OUSOURI,

OUSOURI, a town of Chineſe Tartary; 67 miles S.S.W. of Tondon.

OUSSOOR, a town of Hindooſtan, in Myſore; 69 miles E.N.E of Seringapatam. N. lat. 12° 41. E. long. 77° 52'.

OUST, a town of France, in the department of the Arriege, and chief place of a canton, in the diſtrict of St. Girons; 7½ miles S. of St. Girons. The place contains 1190, and the canton 12,407 inhabitants, on a territory of 525 kiliometres, in 10 communes.

OUSTAD, a town of Norway, in the province of Chriſtianſand.

OUSTED, formed from the French *oſter*, *to remove*, or *take away*, in our *Ancient Law Books*, a being removed, or put out of poſſeſſion.

OUSTER, or DISPOSSESSION, in *Law*, is an injury that carries with it the amotion of poſſeſſion; for thereby the wrong-doer gets into the actual occupation of the land or hereditament, and obliges him that hath a right to ſeek his legal remedy, in order to gain poſſeſſion, and damages for the injury ſuſtained. This ouſter may either be of the freehold by *abatement*, *intruſion*, *diſſeiſin*, *diſcontinuance*, and *deforcement*; or of chattels real, as an eſtate by ſtatute-merchant, ſtatute-ſtaple, or elegit, or an eſtate for years.

An abatement is where a perſon dies ſeiſed of an inheritance, and before the heir or deviſee enters, a ſtranger who has no right makes entry, and gets poſſeſſion of the freehold: this entry of him is called an abatement, and he himſelf is denominated an abator. For the other ſpecies of ouſter, ſee the ſeveral terms that expreſs them.

Ouſter, or amotion of poſſeſſion from eſtates held by ſtatute, recognizance, or elegit, is only liable to happen by a ſpecies of diſſeiſin, or turning out of the legal proprietor, before his eſtate is determined, by raiſing the ſum for which it is given him in pledge. And for ſuch ouſter, though the eſtate be merely a chattel intereſt, the owner ſhall have the ſame remedy as for an injury to a freehold, *viz.* by aſſiſe of novel diſſeiſin. But this depends upon the ſeveral ſtatutes, which recite theſe reſpective intereſts, and which expreſsly provide and allow this remedy, in caſe of diſpoſſeſſion. (The ſtatutes are ſtat. Weſtm. 2. 13 Edw. I. c. 18. Stat. *de mercatoribus*, 27 Edw. III. c. 9. Stat. 23 Hen. VIII. c. 6. § 9.) Upon which account it is that ſir Edward Coke obſerves (1 Inſt. 43.), that theſe tenants are ſaid to hold their eſtates *ad liberum tenementum*, until their debts be paid; becauſe by the ſtatutes they ſhall have an aſſiſe, as tenants of the freehold ſhall have; and in that reſpect they have the ſimilitude of a freehold.

As for ouſter, or amotion of poſſeſſion, for an eſtate for years; this happens only by a like kind of diſſeiſin, ejection, or turning out, of the tenant from the occupation of the land during the continuance of his term. For this injury the law has provided him with two remedies, according to the circumſtances and ſituation of the wrong-doer; the writ of *ejectione firmæ*, which lies againſt any one, the leſſor, reverſioner, remainder-man, or any ſtranger, who is himſelf the wrong-doer, and has committed the injury complained of; and the writ of *quare ejecit infra terminum*, which lies not againſt the wrong-doer or ejector himſelf, but his feoffee, or other perſon claiming under him. Theſe are mixed actions, ſomewhat between real and perſonal; for therein are two things recovered, as well reſtitution of the term of years, as damages for the ouſter or wrong. See EJECTIONE *Firmæ*, and QUARE *ejecit*, &c.

OUSTER *le Main*, *amovere manum*, denotes a livery of lands out of the king's hands; or a judgment given for him that traverſed, or ſued, a monſtrans le droit.

When it appeared upon the matter diſcuſſed, that the king had no right or title to the land he had ſeized, judgment was given in chancery, that the king's hand be amoved. Hereupon, *ouſter le main*, or *amoveas manum*, was awarded to the eſcheator, to reſtore the land, &c.

But now all wardſhips, liveries, *ouſter le mains*, &c. are taken away and diſcharged, by ſtat. 12 Car. II. c. 24.

OUSTER *le Mer*, a cauſe of excuſe or eſſoin; where a man not appearing in court upon ſummons, it is alleged, that he is beyond the ſeas.

OUT, in *Sea Language*, a term implying the ſituation of the ſails, when they are ſet or extended to aſſiſt the ſhip's courſe, as oppoſed to *in*; which is alſo applied, in the contrary ſenſe, to ſignify when ſuch ſails are furled. See IN.

OUT *of Trim*, the ſtate of a ſhip, when her beſt ſailing qualities are retarded by the injudicious arrangement of the maſts and ſails, or ſtowage of her cargo, which will conſiderably affect the ſhip's motion and ſtability.

OUT *of Winding*, in *Ship-Building*, not twiſting, but that the ſurface, whether of timber or plank, be a direct plane.

OUT, *Outſide*, or *Without*, in the *Manege*, is the contrary of *in*, *inſide*, *inner*, &c. See IN, INN, &c.

OUT *Field Land*, in *Agriculture*, a term applied to a ſort of land in Scotland, which is ſimilar to the unincloſed common field-lands in this country. Lord Dundonald remarks, that that part of the farm, called the out field-land, never receives any manure. After taking from it two or three crops of grain, it is left in the ſtate it was in at reaping the laſt crop, without ſowing thereon graſs-ſeeds for the production of any ſort of herbage. During the firſt two or three years, a ſufficiency of graſs to maintain a couple of rabbits *per* acre is ſcarcely produced. In the courſe of ſome years, it acquires a ſward; and after having been depaſtured for ſome years more, it is again ſubmitted to the ſame barbarous ſyſtem of huſbandry.

It was a ſort of diſtinction that exiſted prior to the date of incloſures, and was likewiſe general throughout England. It is wearing out faſt in Scotland, from the ſame cauſes which have operated in England.

OUTAITANI, in *Geography*, a town of Upper Siam; 80 miles N.W. of Louvo.

OUTANULLA, a town of Bengal, on the Ganges; 5 miles S. of Rajemal.

OUTAPALLAM, a town of Hindooſtan; 10 miles E.N.E. of Coimbetore.

OUTARD BAY, a bay of Canada, on the north ſide of the river St. Lawrence. N. lat. 42° 2'. W. long. 68° 15'.

OUT-BOARD, in *Sea Language*, on the outſide of the ſhip, as "the out-board works," &c.

OUTCH, in *Geography*, a province of Hindooſtan, between the rivers Chunaub and Indus, near the ocean.

OUTCHACTAL, a town of Thibet; 67 miles E. of Haracher-Hotun.

OUTCHANG, a town of China, of the firſt rank, in Hou-quang, on the river Yang-tſe; 582 miles S. of Peking. N. lat. 30° 36'. E. long. 113° 50'.

OU-TCHEOU, a city of China, of the firſt rank, in Quangſi. All the rivers of the province unite near this city, which joins to the province of Quang-tong, and is the key of the whole province, and the moſt conſiderable city for commerce in it. Within its juriſdiction are one city of the ſecond order, and nine of the third. The territory is partly mountainous, and partly flat. The mountains furniſh cinnabar, and an uncommon tree, called Quang-lang, which, inſtead

inſtead of pith, has a ſoft pulp, of which they make flour. N. lat. 23° 28′. E. long. 110° 32′. Groſier.

OUTCHOU, a river of Thibet, which runs into the Sampoo.

OU-TCHUEN, a town of the kingdom of Corea, in King-ki; 59 miles S.S.E. of King-ki.—Alſo, a ſea-port town of China, of the third rank, in Quang-tong; 20 miles S.S.E. of Hoa.

OUTEA, in *Botany*, Aubl. Guian. 28. t. 9. Juſſ. 347, a barbarous name, contrived by Aublet out of the Caribean appellation of the tree, *Joutay*. Vahl retains this genus, as diſtinct from the *Vouapa* of the above writer, by the following character.

Calyx turbinate, five-toothed. Petals five; the uppermoſt very large. Stamens four; one of them abortive. Germen ſtalked. *Vahl. Enum. v.* 2. 38.

We are much inclined to the opinion of thoſe who judge this plant to be a *Tamarindus*. See MACROLOBIUM.

OUTEIRO, in *Geography*, a town and fortreſs of Portugal, in the province of Tras los Montes, ſeated on a mountain; 9 miles E.S.E. of Bragança.

OUTER ISLAND, an iſland on the coaſt of Labrador, in the cluſter called St. Auguſtine's Square; S.W. of Sandy iſland.

OUTFANGTHEFE, a privilege whereby a lord was enabled to call any man dwelling in his fee, but taken for felony in another place, to judgment in his own court.

The word is formed from the Saxon *ut, extra, without; fang, capio, vel captus;* and *theof, thief*, q. d. *fur extra-captus*. Spelm.

OUT-FIT, ſignifies the expences of equipping or *fitting-out* a ſhip for ſea, which includes every thing but the hull, ſuch as maſts, yards, ſails, cordage, anchors, artillery, ammunition, and all other naval furniture; with a ſufficient number of men and proviſions.

OUT-HAULER, in *Sea Language*, the rope or tackle made faſt to the tack of the jib, to haul it out by.

OUT-HOLLING, in *Agriculture*, a term provincially applied to the ſhovelling out a ditch, for the uſe of the manure it contains.

OUT-HOUSE, ſuch a building as belongs to, and is placed adjoining to, the dwelling-houſe.

OUTIMACS, in *Geography*, a tribe of American Indians, in the territory of Wayne, between lakes Michigan and St. Clair. The number of warriors is 200.

OUTIN, in *Ichthyology*, a name by which ſome call the fiſh known among authors by the name of *oxyrinchus*.

OU-TING, in *Geography*, a city of China, of the firſt rank, in Yun-nan. N. lat. 25° 53′. E. long. 102° 6′.

OUTLAW, UTLAGATUS, one deprived of the benefit of the law, or put out of the king's protection.

Bracton ſays, an outlaw forfeits every thing he has; and that, from the time of his outlawry, he wears a wolf's head, and any body may kill him *impuné;* eſpecially if he defend himſelf, or fly. But, in the beginning of king Edward III.'s reign, it was reſolved by the judges, that it ſhould not be lawful for any man, but the ſheriff alone, (having lawful warrant for it,) to put to death a man outlawed.

OUTLAWRY, or UTLAWRY, *Utlagaria*, the puniſhment of him who, being called into law, and lawfully ſought, does (after an original writ, and the writs of capias, alias & pluries, returned by a ſheriff with a non eſt inventus, and an exigent, with a proclamation awarded thereupon) contemptuouſly refuſe to appear.

He muſt alſo be called at five county court-days a month between each other; and, if he appear not in that time, *pro exlege tenebitur, cum principi non obediat, nec legi; & extunc exlegabitur; i. e.* he ſhall be pronounced to be out of the king's protection, and deprived of the benefit of the law.

The effect of which is, if he be outlawed at the ſuit of another, in a civil cauſe, he ſhall forfeit all his goods and chattels to the king, and the profits of his land, while the outlawry remains in force; and if in treaſon or felony, all his lands and tenements which he has in fee, or for life, and all his goods and chattels: and in this latter caſe, the law interprets his abſence a ſufficient evidence of his guilt, and without requiring farther proof, accounts him guilty of the fact, on which enſues corruption of blood, &c. And then, according to Bracton, he may periſh without law, &c.

But now, to avoid ſuch inhumanity, it is holden that no man is entitled to kill him wantonly or wilfully; but in ſo doing, he is guilty of murder, unleſs it happens in the endeavour to apprehend him: for any perſon may arreſt an outlaw, either of his own head, or by writ or warrant of *capias utlagatum*, in order to bring him to execution. But ſuch outlawry may be frequently reverſed by writ of error; the proceeding therein being very nice and circumſtantial; and if any ſingle minute point be omitted or miſconducted, the whole outlawry is illegal, and may be reverſed: upon which reverſal, the party accuſed is admitted to plead to, and defend himſelf againſt the indictment.

If after outlawry, in civil caſes, the defendant appears publicly, he may be arreſted by a writ of *capias utlagatum*, and committed till the outlawry be reverſed: which reverſal may be had by the defendant's appearing perſonally in court, (and in the king's bench without any perſonal appearance, ſo that he appears by attorney, according to ſtatute 4 and 5 W. & M. cap. 18.) and any plauſible cauſe, however ſlight, will in general be ſufficient to reverſe it; it being conſidered only as a proceſs to compel appearance. But then the defendant muſt pay full coſts, and put the plaintiff in the ſame condition, as if he had appeared before the writ of *exigi facias* was awarded. It is ordained by Magna Charta, that no freeman ſhall be outlawed, but according to the law of the land.

A minor, or a woman, cannot be outlawed. A woman is ſaid to be *waived*, when a man is outlawed. See WAIVE.

OUTLAWRIES, *Clerk of the*. See CLERK.

OUTLICKER, or OUTLIGGER, in a *Ship*, a ſmall piece of timber, three or four yards long, as occaſion ſerves, made faſt to the top of the poop, and ſtanding right out a-ſtern: at the uppermoſt end of it is a hole, into which the ſtanding part of the ſheet is received, and made faſt through the block of the ſheet; and then again received through another block, which is ſeized to this outlicker, hard by the end of it. This is ſeldom uſed in men of war, or in great ſhips; and whenever it is made uſe of, it is becauſe the mizen-maſt is placed ſo far aft, that there is not room enough within board to hale the ſheet flat.

Outligger ſeems the true orthography of the word, which appears to be derived from the Dutch *uitlegger*, q. d. *outlier*.

OUTLINE, in *Painting* and *Drawing*, is the repreſentation of an imaginary line circumſcribing the boundary of the viſible ſuperficies of objects. It is an arbitrary mode of conveying ideas of form, which has its foundation altogether in art, and was its firſt eſſay towards perfection; and although the progreſs of painting has been ſo great, and it has ſo nearly approached to complete imitation by the help of chiaro-ſcuro and colour, yet outline, ſimple and unaided, ſtill remains duly appreciated, as efficient to produce the greateſt

greateſt and moſt eſſential purpoſes of art, *viz.* the ideas of action and expreſſion in the figures it repreſents.

There is not in fact any ſuch thing as an outline in nature. The effect which natural objects produce upon our viſion, is only that of a number of parts, or of diſtinct maſſes of form and colour, but no lines. We are obliged to aid invention in deſign by reſorting to a fiction; and the firſt and ſimpleſt means which preſents itſelf to the mind is, to ſeparate the objects we deſire to repreſent upon a plane ſurface, by marking the boundary of each, the extreme extent of its dimenſions in every direction; and this we call drawing its outline. We recollect more of a form by its boundary, or its ſeparation from other objects, than by its projecting parts; hence ariſes the ſatisfaction we receive from a line which marks that boundary, though no ſuch line in reality exiſts: our imagination immediately loſes ſight of the fallacy, and dwells upon the form within it. It is ſufficient for this purpoſe, that the exterior of the form be exhibited correct enough to excite an image of the whole; and perhaps the impreſſion a well-drawn outline makes upon the mind, is ſeldom much increaſed, if at all, by the more complete imitation of form which light and ſhade can give it.

Such an outline is in itſelf a perfect thing. It has no exemplar in nature, but is received as an arbitrary token of a ſubſtance. The image it excites, is, indeed, more or leſs perfect, according to the information or force of imagination of the beholder; but as there is no other means of compariſon than with the reaſoning powers of his own mind, its impreſſion muſt be conſidered as complete. Fill it with colour, give the form within it light and ſhade, in ſhort, attempt to make it an imitation of the real object, and it becomes ſubject to compariſons, which in well-informed minds muſt neceſſarily diminiſh its force. Its ſimplicity is the baſis of its power. The impreſſion, as far as it goes, being complete, if the other requiſites of art were not, when added to it, as perfect in their kind as the ſimple outline, it would certainly be weakened in its main points; a more full image might indeed be preſented to the eye, but that fullneſs of effect which ariſes when the mind is ſimply excited to act for itſelf, would be diſturbed, and withdrawn from the pathos of the deſign.

The value of outline will be moſt fully appreciated by thoſe who, with Lavater, have obſerved the fullneſs of character diſplayed in ſilhouettes, or profile outlines filled up with only one colour; and ſtill more by thoſe who have examined the beautiful works in outline from Homer, Æſchylus, and Dante, by Mr. Flaxman. In regarding many of thoſe excellent deſigns, the mind is ſo entirely filled with figure, action, and expreſſion, that it almoſt ſhrinks with fear at the idea of an attempt at further completion.

Though outline is technically employed, or rather conſidered in the arts of deſign, generally, yet it properly belongs only to painting or drawing. Monſ. Wattelet, in the Encyclopédié des Beaux Arts, has given it as his opinion, that the ſculptor has more to do with it than the painter, becauſe, as he has obſerved, every figure wrought in the round has an outline in every view that can poſſibly be taken of it. But, ſurely, this is to confound the offices of the two arts completely. If, as we have defined it, outline is an *ideal line* raiſed by the artiſt to aſſiſt in ſeparating forms, or even to mark the extent of a form, what has the ſculptor to do with it, whoſe occupation conſiſts in producing the forms themſelves, of which in painting it is the arbitrary repreſentative? Lines are the foundation of the painter's art; form, that of the ſculptor. The latter, with the greateſt propriety, takes into his conſideration the full form of his ſubject in every point of view, and to him the outline or boundary is as much an object in the projecting, as in the receding parts; but this varying uſe of the term completely confounds the meaning of it: it is no lo ger the line which ſeparates objects, but the line alſo which marks forms projecting forwards; a thing abſolutely impoſſible to produce by a line, upon a flat ſurface, in many caſes at leaſt, and to be effected only by light and ſhade. Nevertheleſs, the ſculptor may uſefully convert this emblem of form to his own ſervice, by conſidering its effects in all views and combinations of his figures; or what kind of outlines his figures would produce, if taken as a model by a painter; and thus it is technically, though not correctly, employed by him; and ſo far we conſider the French editor as right, when he ſays the ſculptor muſt conſider the contour or outline of his works in every direction, and therefore has a difficult taſk to perform in producing a figure ſufficiently beautiful to bear ſuch a teſt; but when he aſſerts the opinion which gave riſe to theſe obſervations, *viz* that the ſculptor has more to do with outline than the painter, he ſurely forgets, that the latter has to produce the imitation of contour or fulneſs of form over every part of his figures, although he has properly only one outline: and as form only requires attention, at leaſt in this reſpect, in one art, and there is a difficult combination of means requiſite to produce effect in the other, we cannot but think that the painter who aims to be correct has the ſeverer taſk of the two, when the compoſition is once decided upon.

If the art of painting were conſidered merely as an inſtrument of moral inſtruction, or even as a means of relating a fact, outline would be fully adequate to fulfil its purpoſes. But, although we are not inclined to depreciate the value of this noble art, we agree with thoſe who regard its practice more in the light of ornament than of utility, generally ſpeaking; and in that view of it, outline becomes merely a paſſive agent to prepare the way for the more ſplendid effects which chiaro-ſcuro and colour alone can produce.

It is outline which decides the character of a painting; for according to the ſtyle in which this is drawn, muſt be the one adopted in filling up the void; in other words, a figure muſt have complete uniſon in its character; both in parts which appear to come forwards, and are produced within the outline, as well as in thoſe which recede and form it.

As outline is thus eſſentially important in the art, it becomes neceſſarily an object worthy the moſt ſerious attention of the profeſſor, and we cannot recommend to a young practitioner a more uſeful leſſon than that he endeavour to attain, as early as poſſible, the power of drawing an outline free and characteriſtic; as that power can never be unaccompanied with a certain degree of freedom in the execution of a finiſhed picture: but if not attained while the hand is free, and the mind moſt alive to impreſſion, the taſk is rendered proportionably difficult.

What is called acquiring a knowledge of chaſte and true or characteriſtic outline, can be derived from no other ſource than a pure knowledge of beautiful form. The line which deſignates it is of leſs conſequence than the form it circumſcribes, yet it is an agreeable quality in an artiſt to be able to plant a pleaſing image on the mind, by a light, ſkilful, and ſteady hand. There is danger, if the line he draws be too hard, thick, or black, that the figure he intends to convey be forgot in the line: and if too weak, its force may not be adequate to produce the deſired effect.

In the works of artiſts, outline is conſidered in two diſtinct points of view. One is the ſimple and obvious ſenſe of the word, a line marking the form of any given object, ſuch as we have hitherto conſidered it: and various denominations are given to ſuch a line. It is ſaid to be *correct*, *free*, *firm*, *flowing*,

flowing, &c. or the reverſe of either of ſuch qualities. The other is a more arbitrary uſe of it, which is applied to finiſhed pictures; wherein the figures have loſt the marking properly denominated outline, and that name is then applied ideally as it is to objects in nature. Thus, figures in a picture are ſaid to have a hard outline, when the extreme parts are not blended in the ground from which they are relieved, or the ſurrounding parts; or to have a confuſed one, when they are too much ſoftened and loſt in them. The characteriſtic names given to the line itſelf are alſo applied in this caſe, and deſignate the ſtyle of deſign employed in the work; ſuch as graceful, grand, ſevere, decided, &c.; or mean, weak, mannered, incorrect, &c. &c.; for an explanation of which terms we refer to STYLE, in *Deſign*.

In the production of a picture, management of outline conſtitutes a very eſſential part of the difficulties to be contended with, both in the arrangement of the compoſition, and in the completion, for the apparent relief of the objects introduced. In the firſt place, the arrangement of forms or outlines is the main point wherein reſide the expreſſion and character of the ſubject. If it be of the terrific kind, with figures in violent agitation of mind or body, then ſtrong contraſts in the outlines, and involved forms, will enforce its influence. If it be ſimple, grand, or ſevere, the due effect will be moſt readily attained by parallel forms, or nearly ſuch, aſſiſted and united with ſlight contraſts; but if the character be merely agreeable, then lines playfully and gracefully combined, are required to produce an appropriate influence on the obſerver. In the concluſion of the work, the utmoſt attention muſt be paid to the perfection of the outlines, that they be not marked too hard, which would make the effect cutting and diſagreeable to the eye; or too much blended and weakened: in either caſe the great object of relief is counteracted. It muſt be the artiſt's ſteady endeavour to ſteer between theſe two difficulties, but how to effect that deſideratum, to acquire the wiſhed-for medium, depends ſo entirely on a nice obſervance of nature, and on inherent taſte, that it is quite impoſſible to give any poſitive rules concerning it; the painters of the Dutch and Flemiſh ſchools have beſt exemplified it in their works, to the ſtudy of which we recommend our readers.

OUTNESS, is uſed by ſome for that relation of things by which one appears out of, or at a diſtance from, another. Dr. Berkeley, in his "Eſſay on Viſion," makes uſe of the outneſs; and obſerves, that we form no notion of outneſs from the ſenſe of ſeeing merely, but only from motion.

OUT-PARTERS, in our *Ancient Writers*, were a ſort of thieves or highwaymen, on the frontiers of Scotland, who rode about to fetch in ſuch things as they could lay hold on.

OUT-POSTS, in a military ſenſe, a body of men poſted beyond the grand guard, and ſo called, as being without the rounds or limits of the camp.

OUTRAM, WILLIAM, in *Biography*, a learned Engliſh divine, was a native of Derbyſhire, and born in the year 1625. He was entered of Trinity college, Cambridge, where he took his degree of B. A., and of which he obtained a fellowſhip: he afterwards removed to Chriſt's college, where he likewiſe obtained a fellowſhip. In 1649 he took his degree of M. A., and in 1660 that of D. D. He was preſented to the rectory of St. Mary Woolnoth in London; afterwards, in 1669, he was collated to the archdeaconry of Leiceſter, and during the following year he was inſtalled prebendary of St. Peter's church in Weſtminſter. He died in 1679. He acquired celebrity by his ſkill in rabbinical learning, as well as by his acquaintance with the fathers and the ſacred ſcriptures. He was a conſtant and much admired preacher. As a writer, he is entitled to the praiſe of nervouſneſs, preciſion, and accuracy. He was author of a learned work on ſacrifices, entitled "De Sacrificiis Libri duo; quorum altero explicantur omnia Judæorum, nonnulla Gentium profanarum Sacrificia; altero Sacrificium Chriſti. Utroque Eccleſiæ Catholicæ his de rebus Sententia contra Fauſtum Socinum, et ejus Sectatores defenditur," 1677. After his death, a volume of his ſermons was publiſhed, which are good ſpecimens of pulpit compoſitions. Biog. Brit.

OUT-RIDERS, are bailiffs errant, employed by ſheriffs, or their deputies, to ſummon people in the remoteſt parts of their hundreds, to the county or hundred courts.

OUT-RIGGER, in *Ship Building*, a large ſpar, or ſtrong beam of timber, of which there are ſeveral projecting from the ſide of a ſhip, to which the maſts are ſecured in the act of *careening*.

OUT-RIGGER is alſo a ſmall boom, occaſionally uſed in the tops to thruſt out the breaſt-back-ſtays to windward, in order to increaſe their tenſion, and thereby give additional ſecurity to the topmaſt.

OUTSHI-FERMEN, in *Geography*, a town of Little Bucharia; 130 miles E. of Caſhgar.

OUTSHOU, a town of Little Bucharia; 30 miles S. of Caſhgar.

OUTWARD *Flanking Angles*. See ANGLE.

OUT-WORKS, in *Fortification*, all thoſe works made withoutſide the ditch of a fortified place, to cover and defend it. See *Fortification according to M. Vauban's method*; under the article *Military* CONSTRUCTION.

Out-works, called alſo *advanced* and *detached works*, are thoſe which not only ſerve to cover the body of the place, but alſo to keep the enemy at a diſtance, and prevent their taking advantage of the cavities and elevations uſually found in the places about the counterſcarp; which might ſerve them either as lodgments, or as rideaux, to facilitate the carrying on their trenches, and planting their batteries againſt the place. Such are ravelins, tenailles, horn-works, queue d'arondes, envelopes, crown-works. The moſt uſual of theſe are ravelins, or half-moons, formed between the two baſtions, on the flanquant angle of the counterſcarp, and before the curtain, to cover the gates and bridges.

OUVERTURE. See OVERTURE.

OVUM ANGUINUM, a name given by many authors to a foſſil, ſuppoſed by the vulgar to be the petrified egg of a ſerpent, but being really like the brontiæ and ombriæ, ſpecies of the echinites.

This ſome have ſuppoſed to be a bead of glaſs, uſed by the Druids to impoſe upon the vulgar, whom they taught to believe that the poſſeſſor would be fortunate in all his attempts, and that it would give him the favour of the great. See ANGUINUM *Ovum*.

OVUM *Philoſophicum*, or *Chymicum*, is a glaſs body of an oval form, reſembling an egg: uſed for the ſublimation of mercury.

OVUM *Polypi*, in *Natural Hiſtory*, a name given by ſome of the earlier writers to the papyraceous or thin-ſhelled nautilus. The reſemblance of the body and arms of the fiſh which inhabits this ſhell, with thoſe of the ſea-polypus, gave occaſion to their ſuppoſing this creature the ſame animal, not yet got out of the egg. The ſhell of this ſpecies being very thin, and looking like an egg-ſhell, gave farther countenance to this error in leſs knowing ages.

OVUM *Rumphii*, the name of a ſpecies of porcelain ſhell, of the oblong kind, called an *egg*, from its ſhape, by that author. See PORCELAIN *Shell*.

OVUTSI, or OUVUSTI, in *Geography*, a town of Japan, in the iſland of Xicoco. N. lat. 34° 8'. E. long. 135° 20'.

OUZE, in *Agriculture*, a ſort of depoſit made by the ſea, which is often very ſterile and unproductive, but ſometimes the contrary.

OUZELL, BROOK, in *Ornithology*. See RALLUS *Aquaticus*.

OUZELL, *Ring*. See TURDUS *Torquatus*.

OUZELL, *Roſe* or *Carnation-coloured*. See TURDUS *Roſeus*.

OUZELL, *Water*. See STURMUS *Cinclus*.

OUZOUER *ſur Loire*, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the diſtrict of Gien; 6 miles S.E. of Gien. The place contains 686, and the canton 5564 inhabitants, on a territory of 275 kiliometres, in 8 communes.

OW, or AWE, *Loch*, a lake in Argyleſhire, Scotland, extends about thirty miles in length, and is in ſome places two miles broad; but its uſual width does not exceed one mile. It is an uncommonly fine expanſe of water, and little inferior to loch Lomond in the beauty of its ſcenery. A great part of its banks exhibits lofty mountains covered with wood; and within its boſom are many little iſlands ornamented with trees and pictureſque ruins. On Iniſh-Chonnel are the remains of an ancient caſtle belonging to the Argyle family; and on Troach-Elan are veſtiges of another fortreſs, which was granted, with ſome contiguous lands, to the chief of the clan of Mac-Naughton, by king Alexander III., on condition that he ſhould entertain the Scottiſh monarch whenever he paſſed that way. At a more remote period this latter iſland was the Heſperides of Scotland, and the fatal attempt of Troach, to gather its delicious fruit for his beloved Mego, is handed down from age to age in a beautiful Celtic tale, after the manner of Oſſian. "The fair Mego longed for the delicious fruit of the iſle guarded by a dreadful ſerpent. Troach, who had long loved the maid, goes to gather the fruit. By the ruſtling of the leaves the ſerpent was awaked from his ſleep. It attacked the hero, who periſhed in the conflict. The monſter was alſo deſtroyed. Mego did not long ſurvive the death of her lover."

The ſurface of Loch-Awe is 108 feet above the level of the ocean. Numerous rivulets diſcharge themſelves into it on both ſides, and, what is unuſual, it receives a large ſtream at each extremity, emptying itſelf laterally by the river Awe into loch Etive, an arm of the ſea to the north, at a place called Bunaw. This lake abounds with ſalmon, trout, and char. Eels are likewiſe extremely plentiful, but held in great abhorrence by the natives, who regard them as water ſerpents, and unfit for the food of man.

On a rocky point, projecting into the lake, near its eaſtern end, are ſeated the venerable ruins of Caſtle-Kilchurn, which was built in 1440, by the lady of ſir Colin Campbell, knight of Rhodes, and anceſtor of the Breadalbane family, while her huſband was engaged in the holy wars. Since that period, however, many additions have been made to its original extent, by ſucceſſive poſſeſſors. In 1745, it was fitted up for the reception of a royal garriſon to ſecure the peace and tranquillity of the country, but its maſſive walls are now rapidly falling to ruin, and offer to the contemplative mind a melancholy monument of the mutability of earthly grandeur, and of the unavoidable decay of the moſt durable works of human art. Beauties of Scotland, vol. v. Pennant's Tour in Scotland, 4to. 1790.

OWANTY, a town of Lithuania, in the palatinate of Wilna; 16 miles E. of Wilkomierz.

OWARI, a town of Japan, in the iſland of Niphon, ſituated in a bay to which it gives name. N. lat. 35° 30'. E. long. 137° 50'.

OWASCO, a lake of America, partly in the towns of Aurelius and Scipio, in Onondago county, New York, about 11 miles long and one broad; communicating with Seneca river on the N. by a ſtream which runs through the town of Brutus.

OWCE, in *Agriculture*, a provincial word applied to the ox.

OWCH, in *Geography*, a town of Turkeſtan, on a river which runs into the Sihon; 30 miles S.S.E. of Andagan.

OWCZE, a town of Poland, in the palatinate of Podolia; 40 miles W. of Kaminiec.

OWEGO, a poſt-town of America, in Tioga county, New York, on the N.W. bank of the E. branch of the Suſquehannah; 30 miles W. of Union, at Tioga point, containing 1284 inhabitants.

OWEGO *Creek*, a creek of Tioga county, which ſerves as the E. boundary of the townſhip of its name.

OWELTY, or OVELTY *of Services*, in our *Law Books*, an equality of ſervices; as when the tenant paravail owes as much to the meſne, as the meſne does to the lord paramount.

OWEN, JOHN, in *Biography*, a learned Engliſh nonconformiſt divine of the independent denomination, was deſcended from a reſpectable family in North Wales, and born in 1616, at Hadham in Oxfordſhire. At Oxford he received his grammatical learning, and ſo rapid was the progreſs which he made, that at twelve years of age he was admitted a ſtudent at Queen's college. He purſued his ſtudies with incredible diligence, allowing himſelf, for ſeveral years, not more than four hours ſleep in a night. He was, at the ſame time, exceedingly attentive to his health, and occaſionally indulged in ſuch recreations as were proper for ſo robuſt a conſtitution as he enjoyed, ſuch as leaping, throwing the bar, ringing of bells, and ſimilar hardy exerciſes. He was admitted to the degree of B. A. in 1632, and commenced M. A. in 1635. Soon after this, archbiſhop Laud having enjoined the obſervance of ſome new regulations with which Mr. Owen was diſſatisfied, he refuſed ſubmiſſion to them. This conduct greatly offended his uncle, to whom he was already under important obligations for maintaining him at college, and to whom he looked for future aſſiſtance. Being ſuſpected of favouring Puritaniſm, many of his beſt friends abandoned him, and in 1637 his ſituation at college was rendered ſo uneaſy, that he found himſelf obliged to leave it. He was now ordained prieſt, and became chaplain to ſir Robert Dormer of Aſcot in Oxfordſhire, as well as tutor to his eldeſt ſon. Afterwards he was appointed chaplain to lord Lovelace, in whoſe family he reſided at the commencement of the civil wars, when he openly avowed himſelf a friend to the parliamentary cauſe. This conduct was ſo highly reſented by his uncle, who was a zealous royaliſt, that he immediately diſcarded him, ſettled his eſtate upon another perſon, and died without bequeathing him any thing. Lord Lovelace, though he had joined the king's party, continued to treat his chaplain with great civility; but when that nobleman went into the army, Mr. Owen left his houſe, went to London, and became a perfect convert to the principles of the non-conformiſts. Mr. Owen firſt made himſelf known as an author in 1642, by a work entitled "A Diſplay of Arminianiſm," which laid the foundation of his future advancement. He was almoſt immediately preſented to the living of Fordham in Eſſex; and in a ſhort time afterwards to that of Coggleſhall. At this latter place he renounced the Preſbyterian principles, joined

the

the Independents, and formed a church, according to their ſyſtem of diſcipline. Upon the prevalence of the independent party, he was ſent to preach before the parliament on one of the faſt-days in 1646. On this and other occaſions Mr. Owen's ſervices were ſo acceptable to the Commons, that he was afterwards frequently appointed to preach before them, and became the favourite of Fairfax and Cromwell. With the latter he went to Ireland, where he remained a few months, and then returned. He was now called again to preach at Whitehall, and very ſoon after accompanied the protector into Scotland. In 1651 he was promoted to the deanery of Chriſtchurch college in Oxford; when he went to reſide there Cromwell was the chancellor of the univerſity, and he nominated Mr. Owen as his vice-chancellor. In 1653 he was created doctor of divinity by diploma: by virtue of his office as vice-chancellor, he endeavoured to put down habits, formalities, and all ceremonies, notwithſtanding he had before taken an oath to obſerve the ſtatutes, and maintain the privileges of the univerſity. In many reſpects Anthony Wood ſpeaks very diſparagingly, and even contemptuouſly, of Dr. Owen; but other writers, not diſpoſed to eulogize the doctor, applaud the care which he diſplayed in maintaining good diſcipline in the univerſity, and the moderation which he exerciſed towards the king's party. In 1654, when Cromwell ſummoned a parliament, Dr. Owen, it is ſaid by Wood, became a candidate for repreſenting the univerſity, and was elected, but ſat only a very ſhort time in the houſe. This circumſtance is, however, doubted, inaſmuch as it is not referred to by Calamy and other hiſtorians of that period. When Richard Cromwell ſucceeded his father as chancellor of the univerſity, Dr. Owen was removed from the poſt of vice-chancellor, as he was from Richard's favour when he became protector: this is attributed chiefly to the hoſtility of the Preſbyterian party. Dr. Owen was, indeed, one of the leading men in the aſſembly of the Independents, which met at the Savoy in October 1658, and he had a principal ſhare in drawing up a confeſſion of their faith and diſcipline, in oppoſition to the Preſbyterians. While ſteps were purſuing to bring about the reſtoration in 1659, he was ejected from the deanery of Chriſtchurch; upon which he retired to Hadham, where he purchaſed a good eſtate with a handſome houſe. Here he lived for ſome time, preaching in private to many friends, who came from Oxford to hear him, till he was driven away by the ſoldiery. He now removed from place to place, till at length he arrived in London, where, by one of his publications, he became noticed by the lord chancellor Clarendon, who offered to give him preferment, provided he would conform to the church, which the doctor thought proper to decline. From the interruptions to which he was frequently ſubject, he prepared to embark for New England, but was ſtopped by an expreſs order of council. He, about the ſame time, received an offer of a profeſſorſhip of divinity in the United Provinces, which he declined. He continued preaching in a private manner as long as he was able, though it was frequently at the riſk of his perſonal ſafety. In the midſt of the perſecutions of that period, the moderation and learning which he diſplayed procured for him the reſpect and eſteem of ſeveral perſons of honour and quality, who took delight in his converſation, particularly of the earl of Orrery and Angleſea, lord Willoughby of Parham, lord Berkeley, and ſir John Trevor, one of the ſecretaries of ſtate. What is ſtill more wonderful, the king, and James duke of York, paid him particular attention. In one of his conferences with the king, his majeſty aſſured him that he was a friend to liberty of conſcience, and was ſenſible that the diſſenters had met with injurious treatment, at the ſame time preſenting him with a thouſand guineas to diſtribute among thoſe who had ſuffered moſt by the late ſeverities, which royal donation the doctor received with thankfulneſs, and applied with the greateſt fidelity. Dr. Owen died at Ealing on the 24th of Auguſt 1683, in the 67th year of his age. Dr. Owen was tall and graceful in perſon, of a grave and majeſtic countenance, and he poſſeſſed a genteel deportment and manners. His temper was ſerene and even, his diſpoſition liberal, generous, and friendly, and his conduct in the domeſtic relations was peculiarly amiable and affectionate. Of his ardent and unaffected piety, and of his firm and undeviating integrity, his whole hiſtory affords ſufficient evidence. His works are numerous; the chief are "An Expoſition of the Epiſtle to the Hebrews," 4 vols. fol.; "Diſcourſe on the Holy Spirit;" "Treatiſe on Original Sin." All his various writings amount to ſeven vols. in folio, twenty in quarto, and about thirty in octavo. To his great learning and almoſt unceaſing induſtry, his works bear abundant evidence. Dr. Calamy ſays, "he was a man of univerſal reading, and had digeſted it. He was eſpecially converſant in thoſe ſciences that are aſſiſtant to divinity, and maſter of them in an unuſual degree. He was reckoned the brighteſt ornament of the univerſity of Oxford." But another biographer ſays, "he was a perfect maſter of the Latin, Greek, and Hebrew tongues. He was a great philoſopher, and alſo well read in the civil law. A great hiſtorian, having a perfect comprehenſion of church hiſtory in particular. He was thoroughly verſed in all the Greek and Latin poets, well ſkilled in the rabbis, and made great uſe of them as there was occaſion." Anthony Wood, though he has treated his memory with the moſt opprobrious language, ſays, "he had a very graceful behaviour in the pulpit, an eloquent elocution, a winning and inſinuating deportment, and could, by the perſuaſion of his oratory, in conjunction with ſome other outward advantages, move and wind the affections of his admiring auditory almoſt as he pleaſed." Calamy's Ejected Miniſters. Biog. Brit. Granger's Biog. Hiſt. of England.

Owen, John, was a native of Caermarthenſhire, and received his education at Wincheſter ſchool, under Dr. Bilſon. In 1584 he was admitted a fellow of New college, Oxford, where he continued till 1591, when he was appointed maſter of a ſchool near Monmouth. In 1594 he obtained the maſterſhip of the free-ſchool at Warwick, where he made himſelf celebrated by his ſkill in Latin poetry, eſpecially in the epigrammatic kind. He is ſaid to have experienced the poet's fate of perpetual poverty, but he met with a kind friend in biſhop and lord-keeper Williams, by whom he was chiefly ſupported in the later years of his life. He died in 1622, and was buried, at biſhop Williams' expence, in St. Paul's cathedral. His epigrams have been collected in twelve books, and have been publiſhed ſeveral times. It has been ſaid of them, that they are only inferior to thoſe of Martial; but other critics ſay, that "in ſome of his pieces he imitates the pointed turn of Martial with ſucceſs, but the greater number have little to recommend them except the purity and elegant ſimplicity of the language." Several have been tranſlated into the French and Engliſh languages. We ſhall tranſcribe the one which is noticed for containing an elegant compliment to ſir Thomas Overbury's poem, entitled "The Wife," to which we have before referred. See Overbury.

"Uxorem culto deſcribis carmine talem
Qualem oratorem Tullius ore potens;
Qualem deſcribis, quamvis tibi nuberet uxor
Æqualis tali non foret illa virô." Biog. Brit.

Owen, Henry, a learned divine of the church of England.

land, was born near Dolgelly, in Merionethſhire, in the year 1716. He was inſtructed in grammar learning at Ruthin ſchool, in Denbighſhire, and at the age of nineteen he entered himſelf of Jeſus college, Oxford. Among the favourite ſubjects of his purſuit, on his entrance upon academic ſtudies, was that of the mathematics, which he proſecuted with great ardour, and the moſt ſerious application. Having taken his degrees, he turned his attention to the ſtudy of phyſic. For three years he practiſed as a phyſician, which profeſſion he quitted on account of want of health, and then directed his views to the clerical calling. In early life he was chaplain to ſir Mathew Featherſtonehaugh, who preſented him to the living of Torling, in Eſſex. In the year 1748 he publiſhed his "Harmonia Trigonometria, or a ſhort Treatiſe on Trigonometry." In 1750 he was preſented to the rectory of St. Olave, Hart-ſtreet, in the city of London, when he reſigned his living of Torling; after this he was appointed chaplain to the biſhop of Landaff, and in 1753 he proceeded doctor of phyſic at Oxford. Dr. Owen's next publication appeared in 1755, entitled "Obſervations on the Scripture Miracles." This was followed, in 1760, by "Obſervations upon the Four Goſpels." His other principal works were, "An Enquiry into the Septuagint Verſion;" "Sermons preached at Boyle's Lectures," in two vols.; "An Introduction to Hebrew Criticiſm;" "The Modes of Quotation uſed by the evangelical Writers explained and vindicated:" in this work the author chiefly examines thoſe quotations which have been introduced by the evangeliſts, in order to point out the intimate connection between the events of the life of Chriſt and the prophecies recorded in the Old Teſtament; and he concludes with proving that the prophecies in queſtion were juſtly applied to Chriſt, or that they are to be conſidered as referring to him, rather than to ſubjects more nearly connected with the times and the ſituations of the prophets. Beſides the articles already mentioned, Dr. Owen was the author of "A Collation of the Account of the Dedication of the Temple," in Bowyer's and Nichols's "Origin of Printing;" "Remarks on the Time employed in Cæſar's two Expeditions into Britain," in the ſecond volume of the "Archæologia." Dr. Owen had a conſiderable ſhare in preparing for the public eye Mr. Bowyer's "Conjectures on the New Teſtament;" and he aſſiſted Mr. Nichols in editing the 4to. edition of Mr. Bowyer's Greek teſtament in 1783, as we learn from this obſervation in the inſcription of it to Dr. Owen: "Ipſius auxilio concinnatam." He died in the year 1795, in the eightieth year of his age. New Ann. Regiſter.

Owen, in *Geography*, a town of Wurtemberg; 18 miles S.E. of Stuttgart.

Owen's *Bay, St.*, a bay on the W. coaſt of the iſland of Jerſey, with a town or village of the ſame name; 6 miles W.N.W. of St. Helier.

Ower-Gate, in *Rural Economy*, a provincial word ſignifying a ſtile place, or imperfect gap in a hedge, and alſo a ſtepping place over a brook.

Ower-*Welt*, a provincial word applied to a ſheep, which gets laid upon it's back in a hollow.

OWEY, in *Geography*, a ſmall iſland of the Atlantic, near the N.W. coaſt of Ireland. N. lat. 55° 3′. W. long. 8° 21′.

OWHARREE, a harbour on the W. coaſt of Huaheine, one of the Society iſlands, in the South Pacific ocean. S. lat. 16 54′. W. long. 151° 8′.

OWHYHEE, an iſland in the North Pacific ocean, diſcovered by captain Cook, Nov. 30, 1778. This is the eaſternmoſt, and by far the largeſt of the group called Sandwich iſlands; it is of a triangular ſhape, and nearly equilateral. The following particulars relating to this iſland are extracted from the account of it by Capt. King, who viſited it again after the death of Capt. Cook, in March 1779. (See Cook's Third Voyage, vol. iii.) The angular points make the north-eaſt and ſouth extremities, of which the northern is in N. lat. 20° 17′. E. long. 204° 2′: the eaſtern in N. lat. 19° 34′. E. long. 205° 6′.; and the ſouthern extremity in N. lat. 18° 54′. E. long. 204° 15′. Its greateſt length, which lies in a direction nearly N. and S., is twenty-eight leagues and a half, its breadth is twenty-four leagues, and it is about 255 geographical, or 293 Engliſh miles in circumference. The whole iſland is divided into ſix large diſtricts: Amakooa and Aheedoo, which lie on the N.E. ſide; Apoona and Kaoo on the ſouth-eaſt; Akona and Koaarra on the weſt. The diſtricts of Amakooa and Aheedoo are ſeparated by a mountain, called *Mounah Kaah*, or *The Mountain Kaah*, which riſes in three peaks, perpetually covered with ſnow, and may be clearly ſeen at 40 leagues diſtance. To the N. of this mountain the coaſt conſiſts of high and abrupt cliffs, down which fall many beautiful caſcades of water. We were once flattered with the hopes of meeting with a harbour round a bluff head, in N. lat. 20° 10′, and E. long. 204° 26′; but on doubling the point, and ſtanding cloſe in, we found it connected, by a low valley, with another high head to the north-weſt. The country riſes inland with a gentle aſcent, is interſected by deep narrow glens, or rather chaſms, and appeared to be well cultivated, and ſprinkled over with a number of villages. The ſnowy mountain is very ſteep, and the lower part of it covered with wood. The coaſt of Aheedoo, which lies to the ſouth of Mouna Kaah, is of a moderate height, and the interior parts appear more even than the country to the N.W., and leſs broken by ravines. Off theſe two diſtricts we cruized for almoſt a month; and, whenever our diſtance from the ſhore would permit it, were ſure of being ſurrounded by canoes laden with all kinds of refreſhments. We had frequently a very heavy ſea, and great ſwell, on this ſide of the iſland, and as we had no ſoundings, and could obſerve much foul ground off the ſhore, we never approached nearer the land than two or three leagues, excepting on the occaſion already mentioned. The coaſt to the N.E. of Apoona, which forms the eaſtern extremity of the iſland, is low and flat; the acclivity of the inland parts is very gradual, and the whole country covered with cocoa-nut and bread-fruit trees. This, as far as we could judge, is the fineſt part of the iſland, and we were afterward told, that the king had a place of reſidence here. At the ſouth-weſt extremity the hills riſe abruptly from the ſea-ſide, leaving but a narrow border of low ground towards the beach. We were pretty near the ſhore at this part of the iſland, and found the ſides of the hills covered with a fine verdure; but the country ſeemed to be very thinly inhabited. On doubling the eaſt point of the iſland, we came in ſight of another ſnowy mountain, called *Mouna Roa*, or *The Extenſive Mountain*, which continued to be a very conſpicuous object all the while we were ſailing along the ſouth-eaſt ſide. It is flat at the top, making what is called by mariners table-land: the ſummit was conſtantly buried in ſnow, and we once ſaw its ſides alſo ſlightly covered for a conſiderable way down, but the greateſt part of this diſappeared again in a few days. According to the tropical line of ſnow, as determined by Mr. Condamine, from obſervations taken on the Cordilléras, this mountain muſt be at leaſt 16,020 feet high, which exceeds the height of the Pico de Teyde, or Peak of Teneriffe, by 724 feet, according to Dr. Heberden's computation; or 3680, according to that of the chevalier de Borda. The peaks of Mouna Kaah appeared to be about half a mile high, and as they are entirely covered with ſnow, the altitude of their ſummits cannot be leſs than 18,400 feet. But it is probable that both theſe

mountains may be conſiderably higher. For, in inſular ſituations, the effects of the warm ſea-air muſt neceſſarily remove the line of ſnow, in equal latitudes, to a greater height than where the atmoſphere is chilled on all ſides, by an immenſe tract of perpetual ſnow. The coaſt of Kaoo preſents a proſpect of the moſt horrid and dreary kind: the whole country appearing to have undergone a total change from the effects of ſome dreadful convulſion. The ground is every where covered with cinders, and interſected in many places with black ſtreaks, which ſeem to mark the courſe of a lava that has flowed, not many ages back, from the mountain Roa to the ſhore. The ſouthern promontory looks like the mere dregs of a volcano. The projecting head-land is compoſed of broken and craggy rocks, piled irregularly on one another, and terminating in ſharp points. Notwithſtanding the diſmal aſpect of this part of the iſland, there are many villages ſcattered over it, and it certainly is much more populous than the verdant mountains of Apoona. Nor is this circumſtance hard to be accounted for. As theſe iſlanders have no cattle, they have conſequently no uſe for paſturage, and therefore naturally prefer ſuch ground as either lies more convenient for fiſhing, or is beſt ſuited to the cultivation of yams and plantains. Now amidſt theſe ruins there are many patches of rich ſoil, which are carefully laid out in plantations; and the neighbouring ſea abounds with a variety of moſt excellent fiſh, with which, as well as with other proviſions, we were always plentifully ſupplied. Off this part of the coaſt we could find no ground leſs than a cable's length from the ſhore, with 160 fathoms of line, excepting in a ſmall bight to the eaſtward of the ſouth point, where we had regular ſoundings of fifty and fifty-eight fathoms, over a bottom of fine ſand. Before we proceed to the weſtern diſtricts, it may be neceſſary to remark, that the whole eaſt ſide of the iſland, from the northern to the ſouthern extremity, does not afford the ſmalleſt harbour or ſhelter for ſhipping. The S.W. parts of Akona are in the ſame ſtate with the adjoining diſtrict of Kaoo; but farther to the north, the country has been cultivated with great pains, and is extremely populous. In this part of the iſland is ſituated *Karakakooa Bay*, which ſee. Along the coaſt nothing is ſeen but large maſſes of ſlag, and the fragments of black ſcorched rocks; behind which the ground riſes gradually for about two miles and a half, and appears to have been formerly covered with looſe burnt ſtones. Theſe the natives have taken the pains of clearing away, frequently to the depth of three feet and upwards; which labour, great as it is, the fertility of the ſoil amply repays. Here, in a rich aſhy mould, they cultivate ſweet potatoes, and the cloth plant. The fields are incloſed with ſtone fences, and are interſperſed with groves of cocoa-nut trees. On the riſing ground beyond theſe the bread-fruit trees are planted, and flouriſh with the greateſt luxuriance. Koaara extends from the weſternmoſt point of the northern extremity of the iſland; the whole coaſt between them forming an extenſive bay, called *Toe-yah-yah*, which is bounded to the N. by two very conſpicuous hills. Toward the bottom of this bay, there is foul, corally ground, extending upwards of a mile from the ſhore, without which the ſoundings are regular, with good anchorage, in twenty fathoms. The country, as far as the eye could reach, ſeemed fruitful and well inhabited, the ſoil being in appearance of the ſame kind with the diſtrict of Kaoo, but no freſh water is to be got here. A party advanced into the land, to the diſtance of three or four miles from the bay: they found the country as before deſcribed; the hills afterwards roſe with a more ſudden aſcent, which brought them to the extenſive plantations that terminate the view of the country, as ſeen from the ſhips. Theſe plantations conſiſt of the tarrow or eddy-root, and the ſweet potatoe, with plants of the cloth tree, neatly ſet out in rows. The walls that ſeparate them are made of the looſe burnt ſtones which are got in clearing the ground; and being entirely concealed by ſugar canes, planted cloſe on each ſide, make the moſt beautiful fences that can be conceived. The party ſtopped for the night at the ſecond hut they found amongſt the plantations, about ſix or ſeven miles, as they eſtimated the diſtance, from the ſhips. The proſpect from this ſpot was very delightful; they ſaw the ſhips in the bay before them; to the left a continued range of villages, interſperſed with groves of cocoa-nut trees, ſpreading along the ſea-ſhore; a thick wood ſtretching out of ſight behind them; and to the right an extent of ground laid out in regular and well-cultivated plantations, as far as the eye could reach. Near this ſpot, at a diſtance from any other dwelling, the natives pointed out to them the reſidence of an hermit, who, as they ſaid, had formerly been a great chief and warrior, but had long ago quitted the ſhores of the iſland, and now never ſtirred from his cottage. They proſtrated themſelves as they approached him, and afterwards preſented to him a part of ſuch proviſions as they had brought with them. His behaviour was eaſy and cheerful; he ſcarcely ſhewed any marks of aſtoniſhment at the ſight of our people, and though preſſed to accept of ſome of our curioſities, he declined the offer, and ſoon withdrew to his cottage. He was deſcribed as by far the oldeſt perſon any of the party had ever ſeen, and judged to be, by thoſe who computed his age, at the loweſt, upwards of 100 years old. Here the travellers found the cold ſo intenſe, that they could get but little ſleep, and the natives none at all; both parties being diſturbed the whole night by continued coughing. This extraordinary rigour of cold was aſcribed to the eaſterly wind, which blew freſh over the ſnowy mountains. They ſtill proceeded, and entered a thick wood, through which their progreſs was ſlow; and after they had advanced about ten miles in the wood, they found themſelves, on a ſudden, within ſight of the ſea, and at no great diſtance from it. They therefore retraced their ſteps for ſix or ſeven miles to an unoccupied hut, where they had left three of the natives and two of their own people, and the ſmall ſtock that remained of their proviſions. Here they ſpent the ſecond night, ſuffering much from the intenſe cold. Their proviſions being exhauſted, they found it adviſable to return to ſome of the cultivated parts of the iſland, and quitted the wood by the ſame path on which they had entered it. Having obtained a freſh ſupply, they marched along the ſkirts of the wood for ſix or ſeven miles, and entered it again, purſuing their courſe for the firſt three miles through foreſts of lofty ſpice-trees. In paſſing through the woods, they found many canoes half finiſhed, and here and there a hut; but ſaw none of the inhabitants. In their farther progreſs, they experienced the want of water, as in a courſe of 20 miles they had met with no ſprings. In the night the cold was more intenſe than they had found it before, which prevented their deriving much refreſhment from reſt and ſleep. At length they determined to return to the ſhips, after taking a view of the country from the higheſt trees which the place afforded. From this elevation they ſaw themſelves ſurrounded, on all ſides, with wood towards the ſea; they could not diſtinguiſh, in the horizon, the ſky from the water; and between them and the ſnowy mountain, which they had once intended to aſcend and examine, was a valley about ſeven or eight miles broad, above which the mountain appeared only as a hill of a moderate ſize. Finding themſelves about 9 miles N.E. of the ſhips, they directed their march toward them through the plantations.

As

As they paſſed along, they did not obſerve a ſingle ſpot of ground, that was capable of improvement, left unplanted; and, indeed, it appeared from their account hardly poſſible for the country to be cultivated to greater advantage for the purpoſes of the inhabitants, or made to yield them a larger ſupply of neceſſaries for their ſubſiſtence. They were ſurprized to meet with ſeveral fields of hay; and on enquiring to what uſe it was applied, were told, it was deſigned to cover the young tarrow grounds, in order to preſerve them from being ſcorched by the ſun. They ſaw a few ſcattered huts among the plantations, which ſerved for occaſional ſhelter to the labourers; but no villages at a greater diſtance than four or five miles from the ſea. It was on this iſland that the celebrated captain Cook fell a ſacrifice to a miſunderſtanding, or ſudden impulſe of revenge, in the natives, on Sunday the 14th of February, 1779. See his biographical article.

OWL, in *Ornithology*. See STRIX.

OWL, *Churn*, See CAPRIMULGUS *Europæus*.

OWL *Fiſh*, or *Sea Owl*, in *Ichthyology*, an Engliſh name for the lumpus, more frequently called the *lump-fiſh*; and by the Scotch the *cock-paddle*. See CYCLOPTERUS *Lumpus*.

OWL *Pigeon*, in *Ornithology*, the name of a particular ſpecies of pigeon, called by Moore the *columba bubo nominata*. It is a ſmall and ſhort-bodied pigeon; it has a ſhort round head, and has a ſeries of feathers that ſeparate and open two ways upon the breaſt: but its moſt remarkable character is its beak, the upper chop of which is bent, and hooked over like an owl's: this is the occaſion of its name. It is of various colours, as white, blue, or black, but is always of one colour, never pied.

OWL's *Head*, in *Geography*, a cape on the S.E. coaſt of Nova Scotia. N. lat. 44° 42'. W. long. 60° 50'.

OWLAK, a town of Hindooſtan, in Rohilcund; 12 miles E. of Biſſowia.

OWLER, a maſter of a ſhip, or other perſon, who conveys wool, or other prohibited goods, in the night, to the ſea-ſide, in order to ſhip them off contrary to law.

The name is derived hence, that like owls they only ſtir abroad in the night-time.

OWLING, in *Law*, ſo called from its being uſually carried on in the night, denotes the offence of tranſporting wool or ſheep out of this kingdom, to the detriment of its ſtaple manufacture. This was forbidden at common law (Mir. c. 1. § 3.), and more particularly by ſtatute 11 Edw. III. c. 1. when the importance of our woollen manufacture firſt became an object of attention; and there are now many later ſtatutes relating to that offence, the moſt uſeful and principal of which are thoſe enacted in the reign of Elizabeth and ſince. The ſtatute 8 Eliz. c. 3. makes the tranſportation of live ſheep, or embarking them on board any ſhip, for the firſt offence, forfeiture of goods, and impriſonment for a year, and that at the end of the year the left hand ſhall be cut off in ſome public market, and ſhall there be laid up in the moſt open place; and the ſecond offence is felony. The ſtatutes 12 Car. II. c. 32. and 7 & 8 W. III. c. 28. make the exportation of wool, ſheep, or fuller's earth, liable to pecuniary penalties, and the forfeiture of the intereſt of the ſhip and cargo by the owners, if privy; and confiſcation of goods, and three years' impriſonment to the maſter and all the mariners. And the ſtatute 4 Geo. I. c. 1. (amended and further enforced by 12 Geo. II c. 21. and 19 Geo. II. c. 34.) makes it tranſportation for ſeven years, if the penalties be not paid.

OWNER, the proprietor of a ſhip, by whom ſhe is freighted to the merchant for conveyance by ſea.

OWRUCZE, in *Geography*, a town of Lithuania, in the palatinate of Kiev; 96 miles N.W. of Kiev.

OWSCRAW, a town of Hindooſtan, in Bahar; 20 miles W. of Rotas.

OWSE, among tanners, is oaken bark, beaten or ground ſmall to ſerve in the preparation of leather.

OX, Bos, in *Zoology*, a genus of the *Mammalia Pecora*, the characters of which are that it has hollow perſiſtent horns, which are ſmooth, and bend outwards and forwards in a ſemilunar form. It has eight cutting teeth in the lower jaw, none in the upper, and no tuſks. The animals of this genus are extremely uſeful to mankind, ſerving as beaſts of draught and burden, and furniſhing for food beef, milk, cheeſe, butter, curds and whey; their ſkins make excellent leather for many purpoſes (ſee HIDE); the fat is uſed for making ſoap and candles; the horns are manufactured into a variety of uſeful utenſils; and even the hoofs, bones, and hair are converted to uſe. They principally delight in flat paſtures, avoiding woods and ſteep hills; they fight by puſhing with their horns; their voice is denominated "lowing" or "bellowing;" the male is called *Bull* (which ſee); when emaſculated, ox: the female, *Cow* (which ſee); when ſpayed, heifer; the young *Calf* (which ſee): and, like the ſheep, it has various appellations for different ages and circumſtances, as ſteer, ſtot, runt, keillie, ſtirk, ſeg, and many others, which vary in different diſtricts.

The common ox, or Bos *taurus*, has round horns, which are curved outwards; and a pendant dewlap. This ſpecies inhabits almoſt every part of the world, either in a wild or domeſticated ſtate. It is ſubject to great variety in form, colour, and figure of the horns. For the varieties, both of the wild and domeſticated ox or bos, and other ſpecies; ſee TAURUS.

Ox, in *Rural Economy*, the name of a well-known animal, produced from the male of the cattle kind by caſtration. See CATTLE.

Oxen, like other domeſtic animals, vary much in colour; but whatever be the colour, it ſhould be gloſſy, thick, and ſmooth to the touch; for if it be harſh, tough, or thin, there is reaſon to ſuppoſe that the animal is out of order, or at leaſt not of a ſtrong conſtitution.

Mr. Marſhall made many experiments on the utility of oxen in the plough, and ſtrongly recommends the uſe of them for moſt draught purpoſes, as no horſes draw better. He remarks that full-grown oxen in general are much longer made than horſes, too long for common ſhafts, not having room to back the cart; for which reaſon the ſhafts ſhould be made long enough to admit them. Ox-collars are ſtrongly recommended. See COLLARS.

The comparative merits and demerits of beaſts of labour, depend, in his opinion, on their firſt coſt, their keep, their work, and their value after working. A powerful, handſome, ſix-years'-old ox, might formerly be purchaſed for ten or twelve guineas; but a powerful, handſome, ſix-years'-old horſe, would coſt from twenty to twenty-four guineas. Suppoſe that ten guineas a-head are ſaved by purchaſing oxen inſtead of horſes, and that a farmer has occaſion for three teams, he will have an addition, every ten or twelve years, of one hundred and twenty guineas to ſtock and manage his farm with. Their keep depends, in ſome meaſure, on the prices of hay and corn, and on the ſize and voraciouſneſs of the beaſt to be fed. Taking into the account the unavoidable pilfering of carters, perhaps, on an equality of time, an ox may be kept at two-thirds of the expence of a large cart-horſe. In their work, it is unneceſſary here to contend for ſuperiority, but you may aſpire at equality. Oxen are equally tractable and equally verſatile. Their ſtrength depends

pends upon their age and breed, and their activity on their make and ſtrength. A two-years'-old ox is as worthleſs in work as a two-years'-old horſe; and the working of either is unpardonable. An ox does not arrive at full ſtrength, eſpecially if worked while young, until he be ſix years old. At that age, a large deep-cheſted ox is equal in ſtrength to a ſtrong well-made cart-horſe. Mr. Marſhall adds, that he is not ſo partial to oxen as to imagine that they can do whatever horſes can do: he is nevertheleſs nearly poſitive, that whatever farming horſes do, oxen (of a proper age and properly managed) can do. On the road they are, beyond all doubt, equal to horſes, and at plough they are not inferior, except their work be very heavy. In heavy work they will not ſtrive like horſes, but will, in defiance, keep their ſteady pace. In this point of view, and in this only, oxen are unequal to horſes. Indeed he never worked oxen all the year round, as horſes are done, but he has always given them a month's marſhing in the ſpring, and they have generally had ſome idle days in the winter; their fodder, however, in this caſe, has been proportionable.

In the Rural Economy of Yorkſhire, the long agitated diſpute about the ſuperiority of oxen or horſes, as beaſts of draught, may be conſidered with ſingular propriety. But he is afraid even this county will not furniſh us ſufficient evidence for final deciſion.

"Formerly, and from time immemorial, four or ſix oxen in yokes, led by two horſes, alſo double, were the invariable draught or team of the country; not only upon the road, but in ploughing. Even in ſtirring a fallow, four oxen and two horſes were generally conſidered as requiſite. And in breaking up a fallow, two men and a boy were the common attendants of this unweildy, expenſive team.

"At preſent, there is not perhaps, throughout the vale, a ſingle ox employed in tillage: two horſes with whip reins, without a driver, is now the univerſal plough-team for all ſoils, in almoſt every ſtate.

"Upon the road, however, that is to ſay, in farm carriages, oxen are ſtill in uſe; but ſeldom more than a ſingle pair to a carriage; generally at the pole, with two or three horſes at length before them. Beſide, a number of entire horſe-teams now travel upon the road; things which were formerly unknown in the country.

"Even the timber-carriers (an induſtrious wary ſet of men) continue to uſe them; though their ſole employment be upon the road. They not only find them able to ſtand working every day, provided their feet do not fail them: but, what is much in their favour, they are found to ſtand long hours better than horſes going in the ſame paſture. An ox in a good paſture ſoon fills his belly, and lays himſelf down to reſt; whereas a ſhort ſummer's night ſcarcely affords a horſe time enough to ſatisfy his hunger.

"Another advantage of oxen is here held out. In ſtiff pulls of every kind, moſt eſpecially in going up ſteep hills, a pair of oxen is conſidered as a ſheet anchor. Horſes, it is agreed, are fearful, and ſoon loſe their feet in a ſteep ſlippery road; while oxen, where they are unable to proceed, will always ſtand their ground. Indeed, oxen ſeem to be conſidered as eſſentially neceſſary in an aukward hilly country.

"If we had no other ſpecies of animals adapted to the purpoſe of draught in the iſland, nor any one which could be naturalized to the climate, cart-horſes would be truly valuable; they being much ſuperior to the breed of ſaddle-horſes for the purpoſes of draught.

"But it appears to him evident, from the experience he has had, and the obſervations he has made, that were only a ſmall ſhare of the attention paid to the breeding of draught oxen, which now is beſtowed on the breeding of cart-horſes; animals equally powerful, more active; leſs coſtly; equally adapted to the purpoſes of huſbandry (if harneſſed with equal judgment); leſs expenſive in keep and attendance; much more durable; and infinitely more valuable after they have finiſhed their labours; might be produced."

An ox is to draw the plough only from his third to his tenth year, when it will be adviſable to fatten and ſell him, as being then of a better fleſh than if he was kept longer. The age of this creature is known by his teeth and horns. The firſt fore-teeth, which he ſheds at the end of ten months, are replaced by others, larger, but not ſo white; at ſix months the teeth next to thoſe in the middle fall out, and are alſo replaced by others; and in three years all the inciſive teeth are renewed. They are then equal, long, and pretty white; but as the ox advances in years, they wear, become unequal, and black. It is the ſame in the bull and cow: ſo that the growth and ſhedding of the teeth are not affected by caſtration, or the difference of ſexes. Nor is the ſhedding of horns affected by either; as both bull, ox, and cow, loſe them alike at the end of three years; and theſe alſo are replaced by other horns, which, like the ſecond teeth, remain; only thoſe of the ox and cow are larger and longer than thoſe of the bull. The manner of the growth of theſe ſecond horns is not uniform, nor the ſhooting of them equal. The firſt year, that is the fourth of the ox's age, two ſmall pointed horns make their appearance nearly formed, ſmooth, and towards the head terminated by a kind of button. The following year, this button moves from the head, being impelled by a corneous cylinder, which alſo lengthening, is terminated by another button; and ſo on; for the horns continue growing as long as the creature lives. Theſe buttons become annular joints, which are eaſily diſtinguiſhed in the horn, and by which the age of the creature may be readily known; counting three years for the point of the horn to the firſt joint, and one year for each of the other intervals. See AGE *of Neat Cattle*.

The writer of a late treatiſe on cattle ſuggeſts, that "as a labouring animal, for agricultural purpoſes, he is, on the whole, far ſuperior to the horſe. This important poſition has been ſo repeatedly and irrefragably proved, that it ought, at this period, to be fully ſufficient to make the aſſertion to be no otherwiſe diſproved than by a fair adduction of equivalent and contrary facts. If we can produce, in the ox, ſtrength and weight enough for the heavieſt, with ſpeed ſufficient for the lighteſt ſoils, and thoſe joined with the higheſt degree of docility and reſolution, what would the huſbandman more? Let him, under theſe circumſtances, make his calculation between the value of thoſe benefits to be derived from the labour of the horſe and the ox, taking into the account the leſs expenſive keep of the latter, even when corn-fed, and that the profits of breeding and training for ſale the labouring ox would probably equal the ſimilar tranſactions with the horſe." It is added that the blundering abſurdities publiſhed by theoretical advocates for ox-labour have ſerved to miſlead many, and to bring infinite prejudice to the cauſe. We have been gravely inſtructed, that the ox is fitted for the labours of tillage, 'by the unwieldy magnitude of his body, the ſlowneſs of his paces, and the ſhortneſs of his legs!' the very qualities which render him ſo totally unfit for the purpoſe, any otherwiſe than as a wretched ſubſtitute, and which affords the horſe ſo manifeſt a ſuperiority over him. Oxen of this deſcription could only be advantageous for the labours of the field, in times anterior to the great improvements of horſes, and the preſent character of the Britiſh labouring ox, is a direct reverſe of the picture." And we may even go farther, and aſſert, without the ſmalleſt impropriety, that we poſſeſs breeds of neat cattle in this country, well qualified, from

from their conſiderable powers of progreſſion, for the ordinary purpoſes of quick draught, carrying of burdens, or even for the ſaddle. Such are the Devons, Glamorgans, and the lighteſt of the Suſſex cattle. It is not improbable, that ſome of theſe are able to trot ſeven or eight miles within the hour. Three or four years ſince, a Suſſex ox ran four miles over Lewis courſe, for a hundred guineas, which he performed after the rate of fifteen miles *per* hour Cuſtom alone renders the uſe of bullocks for the ſaddle and the coach unapproved and unnoticed, or ſtrange and ridiculous. Over great part of Aſia, immemorial uſage has eſtabliſhed the propriety of employing oxen in both theſe capacities. They have, it is true, in thoſe countries, the biſon and the zebu, a ſpecies of oxen ſuperior to our's in activity and facility of progreſſion, but the compariſon only proves theſe inferior, by no means uſeleſs, even for quick draught. Were it really an object with us to make uſe of bullocks in this way, there can be no doubt of its ſucceſs, if aided by an increaſed attention to their breed and training, and a due meaſure of that liberal treatment which they are accuſtomed to receive in India, where their travelling oxen are curried, clothed, and attended with as much ſolicitude, and much greater kindneſs, than we beſtow on our beſt horſes. The Indian cattle are extremely docile and quick of perception, patient and kind; like the horſe, their chief travelling pace is the trot, and they are reported by thoſe who have ridden them, often to perform journies of ſixty ſucceſſive days, at the rate of thirty to forty-five miles *per* day. It ought not to be forgotten in favour of the ox, that, like the generous horſe, he is honeſt to the laſt, and never ſtops, or ſhews muleiſh or aſinine reſtleſsneſs and diſobedience."

It is likewiſe ſtated that "much is ſaid in favour of the mule and the aſs, on account of the duration of their labour to ſo late a period, and a ſuperiority thence challenged for the mule, even over the horſe; but with the ox age ſeems to form no queſtion, he may, with the utmoſt truth, be ſaid never to grow old, ſince his laſt value is ſuperior to his firſt, and ſince the keeping of his ſucceſſor is, in every view, a benefit to a man, being an animal which exhauſts not like the horſe, but manures and improves the land on which he is fed and ſupported."

The largeſt oxen are to be choſen for work and for feeding, but then it muſt be where there is land rich enough to maintain them. When they are to draw, care muſt be taken to match them well, both for height and ſtrength; for if one be ſtronger than the other, the weakeſt will ſoon be deſtroyed. They muſt never be driven beyond their natural pace, for the beating of them throws them into ſurfeits, and many other diſeaſes. The time of putting oxen to work is at three years old; they muſt be worked gently the firſt year, eſpecially in hot weather, and fed with a large quantity of hay: this will enable them to bear their labour better than graſs; and they ſhould always be kept in a middle ſtate, neither too fat nor too lean. They may be worked till they are ten or twelve years old, and then ſold.

It is obſerved, that meat and fair treatment ſucceed much better with this animal than blows. The beſt way to break a young one to the yoke is to put him to it with an old tame ox of about his own height and ſtrength. If he prove unruly after this, he muſt be kept hungry, and made to feed out of the driver's hand. Oxen are much more profitable to keep than horſes, there being no loſs in them: and an old wrought ox fattening as well as a young one, and being as good meat. Their keeping alſo is cheaper, for they eat no oats: their harneſs and their ſhoes alſo are conſiderably cheaper, and they are not ſo ſubject to diſeaſes. They muſt always indeed have good graſs and good hay, and they are not ſo ſerviceable as horſes, when there is much working in carts, and where the ways are good; but for winter ploughing, where the ground is heavy, an ox will do as much work as a horſe.

Every farmer, who can keep two teams, would do wiſely to have one of them of horſes, and the other of oxen; it is much better to yoke them together by the necks and breaſts, than by the horns, as ſome do; and where a man keeps an ox-team, he ſhould raiſe two oxen and two cow calves every year, to keep up his ſtock; for it is better for a farmer, in all neceſſary things, to be a ſeller than a buyer. Chalky lands ſpoil the feet of oxen more than any other. See TEAM.

Stealing oxen, or creatures of the ox kind, old or young, whether bull, cow, &c. ſtrictly ſo called, ſteer, bullock, heifer, or calf, is now felony without benefit of clergy; as is likewiſe killing any of theſe, with an intent to ſteal any part of their carcaſes. Stat. 15 & 16 Geo. II. cap. 34. and ſtat. 14 Geo. II. cap. 6. See CATTLE.

Ox-*Eye*, in *Sea Language*, a name given by the ſeamen to thoſe dreadful ſtorms that are ſometimes met with on the coaſt of Guinea; for at firſt it appears in the form of an ox's eye, and not much bigger; but it deſcends with ſuch celerity, that in a very little ſpace of time, and often before they can prepare themſelves for it, it ſeems to them to overſpread the whole hemiſphere; and at the ſame time forces the air with ſo much violence, that the ſhips are ſometimes ſcattered ſeveral ways, ſome directly contrary, and ſometimes are ſunk downright.

Ox-*Eye*, in *Optics*. See SCIOPTIC and CAMERA *Obſcura*.

Ox-*Fly*, in *Natural Hiſtory*, a ſpecies of two-winged fly, bred from a fly-worm, hatched under the ſkin of oxen, from the egg of the parent fly lodged there.

The female of this fly makes a number of ſmall wounds in the backs of the horned cattle, and in each of theſe depoſits an egg: which is afterwards hatched by the warmth of the creature's body. As ſoon as hatched, the young worm finds itſelf in a very convenient lodging, and in a way to be furniſhed with all the neceſſaries of life.

The places where they lie are eaſily diſcovered, as there is ever a tumour about them, like that on the foreheads of children from falls; within this, and under the thick ſkin of the creature, is the worm lodged. The country-people know very well that a worm is contained within each of theſe tumours, but they are ſomewhat miſtaken as to the fly it comes from; the gad-fly being the moſt buſy about theſe creatures, and giving them moſt vexation, they naturally enough have ſuppoſed this the produce of the egg of that fly; but this is an erroneous opinion: Mr. Valliſnieri ſeems the firſt who underſtood the true ſtate of the caſe, and he has given a very full and excellent account of it. See BOTTS and OESTRUS.

Ox-*Lips*, in *Botany*. See PRIMULA.

Ox *Mountain*, in *Geography*. a mountain of Ireland, in the county of Sligo, ten miles W.S.W. of Sligo.

OXALATS, in *Chemiſtry*, are combinations of the oxalic acid with the baſes of ſalts. See the baſes reſpectively.

OXALIC ACID, a vegetable acid, naturally formed in the oxalis acetoſella, or wood ſorrel, from which it takes its name.

OXALIC ACID.

It has been diſcovered by Scheele, that this acid can be formed by the action of nitric acid upon ſugar, and ſeveral other vegetable ſubſtances. The merit of this diſcovery was formerly given to Bergman, who firſt publiſhed the method of preparing it.

In order to form this acid with ſugar and nitric acid, let one part of the former be put into a glaſs retort with three parts of the acid of the ſpecific gravity 1.5, and a gentle heat applied: in a ſhort time a briſk effervеſcence enſues, cauſed by the rapid eſcape of nitrous gas and carbonic acid. This proceſs is to be continued till the effervеſcence ceaſes, and the red fumes diſappear; three parts more of nitric acid are then to be added, when a freſh but leſs violent action will take place, this being continued till the fumes ceaſe, and the liquid becomes colourleſs. It may now be left to cool, when cryſtals of oxalic acid will be depoſited. If the remaining liquor be again treated with nitric acid, it will be rendered capable of affording more cryſtals. When the cryſtals are ſeparated, they ſhould be diſſolved in diſtilled water, and cryſtallized a ſecond time, and in ſome caſes a third cryſtallization may be neceſſary. When they are of a pearly white colour, they may be deemed pure oxalic acid. At firſt view the cryſtals appear like a maſs of needles, but upon cloſe examination they will be found to be four-ſided priſms. They are exceedingly ſharp and acrid to the taſte. They diſſolve in their own weight of boiling water, and in twice their weight of water, at 60°. The ſolution, when ſufficiently diluted, has an agreeably acid taſte. One part of boiling alcohol diſſolves .56 of oxalic acid. It changes vegetable blues to red, and one part gives a ſenſible acidity to .2633 of water. The cryſtallized acid, according to Dr. Thomſon, conſiſts of 77. real acid and 23 water. The cryſtals are not changed by expoſure to the air. When expoſed to heat it gives out diſagreeable pungent fumes of a white colour. It would appear that in this change the water of cryſtallization eſcapes, carrying off a portion of the acid, for the reſiduum is whiter than the cryſtals, and the water is reabſorbed from the atmoſphere, giving it its original properties. When expoſed to diſtillation it firſt undergoes the change above-mentioned. A portion of the acid is ſublimed without alteration. The remainder is decompoſed, affording a dark coloured reſiduum, carbonic acid, carburetted hydrogen, and probably carbonic oxyd.

It oxydates moſt of the metals, as gold, platina, ſilver. Mercury and ſeveral others are exceptions.

It combines with the alkalies, earths, and metallic oxyds, forming ſalts called oxalats.

Although the acid has been formed in the preſence of nitric acid, yet when it is heated with freſh ſtrong acid, mutual decompoſition takes place, and the oxalic acid is converted into carbonic acid and water.

The ſulphuric acid partly decompoſes it when heat is applied, but the change appears to be ſimilar to that produced by heat alone.

The muriatic acid diſſolves it without changing its properties.

The conſtituents of this acid, as well as the reſt of the vegetable acids, have not as yet been determined with preciſion.

An analyſis, given by Fourcroy and Vauquelin, determines it as follows:

Oxygen	77
Carbon	13
Hydrogen	10
	100

A more recent analyſis, by Dr. Thomſon, ſtates it to conſiſt of

Oxygen	64
Carbon	32
Hydrogen	4
	100

This laſt is nearer the truth. We have, however, a ſtill later analyſis by Gay Luſſac and Thenard, by a new mode of operating, with hyper-oxymuriat of potaſh. The proportions determined by theſe laſt chemiſts are,

Oxygen	70.69
Carbon	26.59
Hydrogen	2.72
	100.

In theſe experiments, upon analyſis, it will be more certain to operate upon ſome of the oxalats, rather than upon the free acid, except its water of cryſtallization could be accurately determined. Another objection is its ſubliming before it is decompoſed, which is not the caſe when the acid is combined. The oxalat of lime has been employed for this purpoſe. The oxalats of lead, mercury, and perhaps ſilver, might be employed to advantage when they are well defined.

This, like all other chemical compounds, muſt be conſtituted by limited proportions of its elements, which are oxygen, hydrogen, and carbon. It appears, from the proportion in which it combines with the different ſaline baſes, to have the lighteſt atom of any of the vegetable acids. If we call hydrogen 1, its atom is about 20.

The atom of ſugar, according to a late analyſis by Gay Luſſac and Thenard, is 50 oxygen, 42 carbon, and 6.96 hydrogen. This nearly agrees with one atom of each. We have ſeen that oxalic acid is formed by the mutual decompoſition of ſugar and nitric acid. Although in this decompoſition carbonic acid is evolved, it does not appear that its evolution is eſſential to the formation of oxalats. If the proceſs could be ſo conducted that an atom of oxygen might be transferred from an atom of nitric acid to an atom of ſugar, it would form an atom of oxalic acid, while an atom of nitrous gas eſcapes. The atom of oxalic acid may, therefore, be regarded as conſtituted by an atom of ſugar and an atom of oxygen; the firſt being 5.4 of carbon, 7 of oxygen, and 1 hydrogen. This, added to an atom of oxygen from the acid, will be $5.4 + 2 \times 7 + 1 = 20.4$ the atom of oxalic acid. From theſe data its proportions *per cent.* will be

Oxygen	68.6
Carbon	26.5
Hydrogen	4.9
	100.

This agrees remarkably with the laſt analyſis by the French chemiſts.

From the numbers which may be given to the citric and tartaric acids in their ſaline combinations, the former being about 34, and the latter 45, we may preſume the citric acid to be formed by 2 atoms of ſugar and 1 of oxygen, which will give $(7 + 5.4 + 1) \times 2 + 7 = 33.8$. The tartaric acid appears to conſiſt of 3 atoms of ſugar with 1 of oxygen, or $(7 + 5.4 + 1) \times 7 = 47.2$.

The oxalic acid is principally uſed as a chemical agent.

From the very inſoluble compound which it forms with lime, it is a valuable teſt of the latter ſubſtance. It muſt, however, be obſerved, that the ſuper-oxalat of lime is ſoluble, hence the acid ſhould not be uſed in exceſs. The proper way is to uſe the oxalat of ammonia.

It has the property of diſſolving the red oxyd of iron in common with the citric and tartaric acids, but in a greater degree. If it could be made cheap, it would be a valuable acquiſition to the calico printers.

OXALIS, in *Botany*, from ὀξυς, *ſour*, a name adopted from the Greeks; whoſe ὀξαλις, however, is probably the *Acetoſa* of the Latins, and belongs to the genus *Rumex*; the genus of which we are to treat being ſcarcely diſcoverable in the writings of the ancients, and the firſt of its ſpecies which drew the attention of the earlier modern botaniſts, having been called in their works by various names of their own invention, not worth ſcrutinizing. Poſſibly this may be the *Oxys* of Pliny, which he ſays bore ternate leaves, and was given to perſons with weak ſtomachs.—Linn. Gen. 231. Schreb. 311. Willd. Sp. Pl. v. 2. 772. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 491. Ait. Hort. Kew. ed. 2. v. 3. 116. Juſſ. 270. Lamarck Illuſtr. t. 391. Gærtn. t. 113. (Oxys; Tourn. t. 19.)—Claſs and order, *Decandria Pentagynia*. Nat. Ord. *Gerania*, Juſſ. Rather perhaps allied to his *Rutaceæ*.

Gen. Ch. *Cal.* Perianth of five, rather ſhort, permanent leaves. *Cor.* Petals five, obovate, obtuſe, emarginate, ſpreading; their claws erect, and often cohering. *Stam.* Filaments ten, erect, awl-ſhaped, the five alternate ones ſhorteſt, all frequently combined at the bottom, the longeſt ſometimes furniſhed with a prominent tooth; anthers verſatile, elliptical, two-lobed, furrowed. *Piſt.* Germen ſuperior, with five angles; ſtyles five, thread-ſhaped, various in length with regard to the ſtamens; ſtigmas obtuſe. *Peric.* Capſule membranous, with five angles, five cells, and five valves, burſting longitudinally at the angles. *Seeds* one or more in each cell, roundiſh, ſlightly compreſſed, poliſhed, widely diſperſed, by means of a bivalve elaſtic tunic.

Eſſ. Ch. Calyx of five leaves. Petals five, connected by their claws. Stamens unequal, partially combined at the baſe. Capſule ſuperior, of five cells, burſting at the five angles. Seeds with an elaſtic tunic of two valves.

This curious and pretty genus, of which only 13 ſpecies are found in the firſt edition of the *Species Plantarum*, is augmented to twice that number in *Syſt. Veg.* ed. 14. The diſcoveries of recent botaniſts, at the Cape of Good Hope, have added a much greater number to the original ſtock. Jacquin, in a valuable quarto monograph on the genus, deſcribes 96. Willdenow reduces them to 93, and of theſe 58 are, or have been, cultivated in the Royal Gardens at Kew. Two are natives of Britain; 13 of America; one of the Eaſt Indies; the reſt of the Cape of Good Hope. Nearly all the latter perhaps have bulbous roots, and grow in ſandy ground, flowering after the rainy ſeaſon, their economy being like that of the Cape bulbs, properly ſo called, which belong to the natural order of ENSATÆ. (See that article.) In England they may be preſerved in the greenhouſe, and will bloſſom either very late in autumn, or early in the ſpring. After flowering, the pots require to be kept without water till Auguſt, about which time the roots will put forth freſh leaves. The Cape ſpecies ſcarcely ever produce ſeeds in Europe, nor do they indeed all readily flower, without a great degree of heat, though moſt of them ſucceed by being placed in a glaſs frame, after they have put forth leaves in pots in the open air. The ſpecies are arranged by their leaves, which in moſt are ternate. *O. ſenſitiva* alone, the Eaſt Indian one, has pinnate foliage. Three have ſimple, four twin, and ſix digitate leaves. A few examples will illuſtrate each of the ſections, which are nine in all.

Sect. 1. *With ſimple Leaves.*

O. *monophylla.* Simple-leaved Wood Sorrel. Linn. Mant. 241. Thunb. Oxal. 8. t. 1. f. 1. Jacq. Oxal. 56. t. 79. f. 3. Willd. n. 1. Ait. n. 1.—Stem none. Stalks ſingle-flowered. Leaves elliptical, obtuſe. Filaments ſmooth.—Native of ſandy hills at the Cape. Sent by Mr. Maſſon to Kew in 1774, where it is ſaid to have flowered in October and November. The *bulb* is ovate, about as big as a hazel-nut, with a very fibrous coat. *Leaves* four or five, ſcarcely an inch long, entire, finely downy at the edges only, on ſtalks about the ſame length. *Flower-ſtalks* taller than the leaves, round, downy. *Calyx* downy. *Corolla* pale purple, an inch long, with yellow claws. *Stamens* much ſhorter than the corolla, all ſmooth; five of them very ſhort, the reſt riſing much above the *ſtyles*, which are clothed at the top only with glandular hairs. *Stigmas* obtuſe, downy.

O. *lepida.* Jacq. t. 21, and *roſtrata*, t. 22, ſeem to us too nearly related to the above. There is in fact not the leaſt difference between any of them, except in the *ſtamens* and *ſtyles*. In *lepida* five of the *ſtamens* are extremely ſhort, and the reſt but half the length of the *ſtyles*, which in this ſpecies are remarkably long, ſtraight, and perfect, covered, like the longer ſtamens, with glandular hairs; their *ſtigmas* large and bearded. In *roſtrata* the *ſtyles* are extremely ſhort, ſmooth, and turned out horizontally between the *ſtamens*; the five ſhorteſt of which riſe far above them, and the five longeſt, which are hairy, more than twice as far, ending in a very peculiar glandular tip above each *anther*. This appendage is analogous to what is ſeen in the New Holland genus *Boronia*, and has been cited, by the writer of the preſent article, as one indication, amongſt others, of the affinity between theſe two genera, which their mutual acidity countenances. In the preſent caſe he hazards another conjecture, that the two ſpecies of *Oxalis* in queſtion may be ſexual varieties; in one of which, effectually male, *roſtrata*, the *ſtamens* are moſt perfect; in the other, *lepida*, the *piſtils*. Experience only can ſettle this curious queſtion, which appears not to have entered into the mind of their cultivator and deſcriber, Jacquin. *O. monophylla* ſeems to be the natural or ordinary ſtate of the ſame plant, in which the *ſtamens* and *ſtyles* bear that due proportion to each other, obſervable in other ſpecies.

Sect. 2. *With twin Leaves.*

O. *aſinina.* Aſſes-eared Wood Sorrel. Jacq. t. 24. Willd. n. 4. Ait. n. 3.—Stem none. Stalks ſingle-flowered. Leaflets elliptic-lanceolate. Five of the ſtamens glandular, and taller than the ſtyles.—From the Cape. The *leaves* are numerous, each pair on a winged obovate foot-ſtalk; *leaflets* glaucous, two inches or more in length, with white, crenate, cartilaginous edges. *Flowers* yellow, on ſtalks rather taller than the foliage. Five of the *ſtamens* very ſhort and ſmooth; the reſt glandular, with a ſmooth projection at their baſe, and riſing to nearly twice the height of the *ſtyles*, which ſeems to be their moſt proper and uſual proportion in this genus.

We cannot but make the ſame remark as in the former ſection, reſpecting *lanceæfolia*, (an ill-conſtructed name), Jacq. t. 26; which though ſubject to have ſome ternate *leaves*, ſcarcely differs otherwiſe from the *aſinina*, except in having the *ſtamens* all ſmooth, without a projection at the baſe, and nearly of equal length, ſeemingly feeble and imperfect, while the vigorous *ſtyles* riſe much above them,

and, if we miſtake not, indicate this to be the female plant, the former the male.

O. *criſpa*, t. 23, and *leporina*, t. 25, two whitiſh-flowered ſpecies of this ſection, in both which the *ſtyles* ſurmount all the *ſtamens*, may probably be diſtinct, as differing conſiderably in their *leaves*, though otherwiſe nearly related to each other.

Sect. 3. *With ternate Leaves, and a ſingle-flowered Stalk.* Here Willdenow has thirty-two Species.

O. *fabæfolia*. Bean-leaved Wood Sorrel. Jacq. t. 27. Willd. n. 8. Ait. n. 7.—Stem none. Stalk ſingle-flowered. Leaflets obovate, emarginate, on winged footſtalks.—Nearly allied to *aſinina*, though unqueſtionably a very diſtinct ſpecies. The *leaflets* are ternate, broad, obovate and emarginate, quite entire, without any cartilaginous edge. Wings of the *footſtalks* alſo very broad. *Flowers* yellow, very pale at the back. *Stamens* all glandular and rather ſhort, with five prominent teeth at the baſe. *Styles* of an intermediate length between the longer and ſhorter ſtamens.

O. *ſanguinea*. Bloody-leaved Wood Sorrel. Jacq. t. 29. Willd. n. 10. Ait. n. 9. —Stem none. Stalks ſingle-flowered. Leaflets oblong, obtuſe, downy; the lateral ones dilated, the middle one contracted, at the baſe. Styles and longer ſtamens hairy.—With this we would unite *laburnifolia*, Jacq. t. 28, as differing chiefly in having the *ſtyles* longer than any of the *ſtamens*, whereas in t. 29 they are intermediate between the longer and ſhorter. The herbage of both is downy. *Footſtalks* and backs of the *leaves* deep red. *Petals* yellow, externally downy. There are a few glandular hairs, beſides the ſimple ones, on the *calyx* of *laburnifolia*, and the teeth of its longer *ſtamens* are rather ſhorter and thicker than in the other, which, all things conſidered, only ſhews thoſe characters to be variable.

O. *Acetoſella*. Common Wood Sorrel. Linn. Sp. Pl. 620. Sm. Fl. Brit. n. 1. Engl. Bot. t. 762. Curt. Lond. faſc. 2. t. 31. Woodv. Med. Bot. t. 20. Fl. Dan. t. 980. Willd. n. 25. Ait. n. 18. Jacq. t. 80. f. 1. (Oxys alba; Ger. em. 1201.)—Stem none. Stalks ſingle-flowered. Leaflets inverſely heart-ſhaped, hairy. Styles and ſtamens ſmooth. Root of ſcaly joints.—Native of ſhady groves in moſt parts of Europe; frequent with us in the ſpring. The *root* is remarkable for being jointed, or compoſed of ſmall cluſters of fleſhy ſcales, connected by a thread-like ſtalk. *Leaves* on long, weak, hairy, wavy ſtalks; their *leaflets* drooping, folded, purple at the back. *Flower-ſtalks* taller than the leaves, each bearing a delicate drooping inodorous *flower*, whoſe white or bluſh-coloured *petals* are veined with purple. The longer *ſtamens* are equal to the *ſtyles*, and all are ſmooth. The *capſules* dart forth their *ſeeds* at the ſlighteſt touch, by means of their elaſtic *arillus*, or tunic. Some old authors have named this plant *Lujula*, which the Italians are ſaid to have metamorphoſed into *Alleluia*; and then, to account for this novel appellation, they ſuppoſed it aroſe from the flowers appearing at the ſeaſon when *Alleluia* was ſung in their churches! The *leaves* poſſeſs an agreeable acidity, mixed with aſtringency, and their conſerve, made with fine ſugar, has the flavour of green tea. Its qualities are cooling and refreſhing, but the abundance of common fruits which have the ſame properties, has ſuperſeded the medicinal uſe of this very grateful preparation.

O. *marginata*. Bordered Wood Sorrel. Jacq. t. 68. Willd. n. 27.—Stem none. Flower-ſtalk ſingle-flowered, but half the length of the footſtalks. Leaflets ſquariſh, emarginate. Calyx fringed. Stamens without teeth.—The *root* is bulbous, with a ſmooth coat. *Leaves* dark green, downy, broad and ſhort, on red ſtalks, forming a denſe tuft. *Flowers* white with ſtreaked claws, large, on ſhort declining ſtalks. The *ſtyles* in this are of intermediate length between the *ſtamens*. In *pulchella*, Jacq. t. 69 Willd. n. 28. Ait. n. 19, they riſe much above all the *ſtamens*. This latter therefore we cannot but conſider as a mere female variety, there being nothing that indicates a ſpecific difference, but rather a peculiar conformity, in the reſt of the plant.

Sect. 4. *With ternate Leaves, and a many-flowered Stalk.* Nine Species in Willdenow.

O. *megalorrhiza*. Great-rooted Wood Sorrel. Jacq. Oxal. 33. Willd. n. 42. (Oxys luteo flore, radice craſſiſſimâ; Feuill. Peruv. v. 2. 734. t. 25.)—Stem none. Stalk umbellate. Leaflets inverſely heart-ſhaped. Root very thick, much branched at the ſummit.—Native of the mountains of Peru. It is known only from the figure and deſcription in Feuillée, but the very large, branched, fleſhy *root*, running deep into the earth, and dividing into many thick heads at the ſummit, is altogether peculiar in this genus. The *ſtalks* of the *leaves* and thoſe of the *flowers* are each about three inches high. The *petals* are yellow, with red veins.

O. *tetraphylla*. Four-leaved Wood Sorrel. Cavan. Ic. v. 3. 19. t. 237. Willd. n. 43, ſeems a moſt trifling variety of the following, which happens to have ſometimes four *leaflets* on a ſtalk. Cavanilles ſaw it in the garden at Madrid, to which it was ſent from Mexico.

O. *violacea*. Violet American Wood Sorrel. Linn. Sp. Pl. 621. Jacq. Hort. Vind. v. 2. 84. t. 180. Oxal. t. 80. f. 2. Willd. n. 44. Ait. n. 24.—Stem none. Stalk umbellate, many-flowered. Flowers drooping. Leaves inverſely heart-ſhaped, fringed. — Native of Virginia and Canada. Mr. Aiton, like Jacquin, marks it as a greenhouſe plant, flowering in May and June. The *roots* are bulbous, aggregate, with interſperſed ſcales. *Leaves* numerous, fringed, broadly obcordate, on ſtalks about a ſpan high. *Flower-ſtalks* rather taller, umbellate, ſometimes, but not conſtantly, forked, with a ſolitary intermediate *flower*. The *bloſſoms* are at firſt drooping, then erect, with delicate, recurved, ſtriated, light purple *petals*. Tips of the *calyx-leaves* ſometimes abrupt and glandular.

Sect. 5. *With ternate Leaves, ſingle-flowered Stalks, and a Stem naked below.* Fifteen Species.

O. *ciliaris*. Fringe-leaved Wood Sorrel. Jacq. t. 30. Willd. n. 49. Ait. n. 29.—Stem erect, ſimple. Leaves cluſtered at its top. Leaflets elliptic-oblong, emarginate, hairy. Bracteas linear, cloſe to the flower.—From the Cape. Sent by Mr. Maſſon in 1793. The *root* is a ſmooth *bulb*. *Stem* three or four inches high, almoſt leafleſs, except at the top, where is a cluſter of numerous, glaucous, downy, ternate *leaves*, of a nearly elliptical form, with a notch at the end. *Flowers* red, on ſimple *ſtalks* taller than the *leaves*, with a pair of oblong linear *bracteas* cloſe to the *calyx*. The *ſtyles* riſe above all the *ſtamens*, and like them are hairy.

O. *arcuata*. Glandular Wood Sorrel. Jacq. t. 31, Willd. n. 50. Ait. n. 30.—Stem decumbent, ſimple, naked below.—Leaves cluſtered at its top. Leaflets linear, emarginate, hairy. Bracteas linear, cloſe to the flower.—Nearly allied to the laſt, but probably a diſtinct ſpecies. We cannot but conſider it however as the male plant of *O. linearis*, Jacq. t. 32, for the ſame reaſons that have led to our preceding opinions. The *ſtyles* are very ſhort in *arcuata*, very long in *linearis*.

O. *natans*. Floating Wood Sorrel. Linn. Suppl. 243.

Willd. n. 58. Ait. n. 35. Thunb. Oxal. 9. t. 1. f. 4. Jacq. t. 76. f. 2.—Stem floating, naked below. Leaves cluſtered at its top. Leaflets inverſely heart-ſhaped, ſmooth. Calyx ſmooth.—Native of pools and ditches at the Cape; the ſlender *ſtem* varying in length according to the depth of the water, the tufts of *leaves* floating on the ſurface. *Flowers* erect, white, yellowiſh at the baſe, on ſimple ſtalks, ſcarcely ſo long as the *leaves*. The *footſtalks* in our ſpecimens are hairy, eſpecially their ſummits cloſe to the *leaflets*.

O. *verſicolor*. Striped-flowered Wood Sorrel. Linn. Sp. Pl. 622. Willd. n. 6. Ait. n. 37. Sm. Ic. Pict. t. 7. Curt. Mag. t. 155. Jacq. t. 36. and t. 77. f. 4.—Stem weak, naked below. Leaves cluſtered about its top. Leaflets linear, emarginate, with two callous points beneath.—An elegant ſpecies, conſpicuous for the crimſon margins of the white *petals*, which give the buds a ſpirally ſtriped appearance.

Sect. 6. *With ternate Leaves, ſingle-flowered Stalks, and a leafy Stem.* Twelve Species.

O. *tubiflora*. Tube flowered Wood Sorrel. Jacq. t. 10. Willd. n. 67. Ait. n. 44.—Stem erect, ſomewhat branched, leafy, hairy. Leaves nearly ſeſſile, alternate. Leaflets linear-wedge-ſhaped, recurved. Tube of the flower much longer than its border.—The *ſtem* is about a foot high, round, hairy, beſet with numerous, ſcattered, ſmall, nearly ſeſſile, hairy, narrow, ternate *leaves*. *Flower-ſtalks* axillary, ſolitary, many times longer than the leaves. *Flowers* crimſon; their claws united into a cylindrical downy tube, conſiderably above an inch long, and nearly twice the length of the limb. Willdenow unites with this Jacquin's *caneſcens*, t. 11, whoſe *flower* is of rather a more blueiſh purple. In both the *ſtyles* are ſhorter than any of the *ſtamens*, and we venture to eſteem them male plants; *macroſtylis* of the ſame author, t. 9, in which the *ſtyles* riſe above all the *ſtamens*, being the female. Theſe two plants are ſo exactly the ſame, that nothing but a determination to aſſume an arbitrary character, and to carry it through in ſpite of nature, could induce any perſon to ſeparate them. *O. ſecunda*, t. 12, is probably another variety.

Dr. Sims in Curt. Mag. under *O. rubella*, t. 1031. Jacq. t. 16. Willd. n. 70. Ait. n. 47, has remarked that *hirta*, t. 13, and *roſacea*, t. 17, of Jacquin, are very nearly allied to that ſpecies. We cannot but agree to this, and if we were writing a complete hiſtory of the genus, we might perhaps reduce ſome other ſuppoſed ſpecies to the ſame. *O. hirta*, by its long *ſtyles*, ſeems a female variety.

Sect. 7. *With ternate Leaves, many flowered Stalks, and a Stem.* Sixteen Species.

O. *ſtricta*. Yellow Upright Wood Sorrel. Linn. Sp. Pl. 624. Willd. n. 80. Ait. n. 52. Jacq. t. 4.—(O. corniculata; Fl. Dan. t. 873. O. ambigua; Saliſ. Tr. of Linn. Soc. v. 2. 242. t. 23. f. 4.)—Root creeping. Stem erect, branched. Leaflets inverſely heart-ſhaped. Umbels ſtalked, axillary, ſolitary, many-flowered.—Native of North America, now naturalized as a weed in many Engliſh gardens. *Roots* widely creeping, perennial. *Stems* a foot high, or more, quite erect, ſlightly branched, leafy, round, reddiſh, ſucculent, ſmooth or downy. *Leaves* numerous, ſcattered, on long ſtalks. *Umbels* ſolitary, on long, axillary, ſolitary ſtalks, about equal to the *footſtalks*, but ſtraighter. *Flowers* numerous, ſmall, yellow. *Styles* about as long as the longer *ſtamens*, hairy.—The name of *ſtricta* well diſtinguiſhes this from the following, for which ſome have miſtaken it.

O. *corniculata*. Yellow Procumbent Wood Sorrel. Linn. Sp. Pl. 623. Willd. n. 81. Ait. n. 53. Jacq. t. 5. Engl. Bot. t. 1726. (O. puſilla; Saliſ. Tr. of Linn. Soc. v. 2. 243. t. 23. f. 5. O. lutea; Ger. em. 1202.)—Stem branched, creeping, diffuſe. Leaflets inverſely heart-ſhaped. Umbels ſtalked, axillary, ſolitary, of few flowers.—Native of various parts of Europe. Found abundantly naturalized, if not wild ſtate, in Devonſhire and other ſouthern parts of England, flowering from May to October. The long, trailing, creeping *ſtems*, and the fewer *flowers* in each *umbel*, diſtinguiſh it from the laſt. The name of *corniculatum* has remained with this, becauſe old authors called it *Trifolium corniculatum*, alluding to the long ſeed-veſſels. Both theſe laſt are acid, and might ſupply the place of *O. Acetoſella*, if wanted for medical uſe.

O. *Barrelieri*. Twin-cluſtered Wood Sorrel. Linn. Sp. Pl. 624. Willd. n. 86. Jacq. t. 3. (Trifolium acetoſum americanum, rubro flore; Barrel. Ic. t. 1139.)—Stem erect, branched, leafy. Leaflets ovate, acute, ſtalked. Cluſters in pairs, on a ſolitary axillary ſtalk.—Native of the hotter parts of South America. We have it not in our gardens. Jacquin has it in his ſtove, and complains of the difficulty of ſaving ſeeds, as the capſules are ſo elaſtic. The *root* is fibrous and annual. *Stem* twelve or eighteen inches high, hairy, branched, leafy. *Leaves* on long ſtalks; *leaflets* ovate, acute, entire; the terminal one on a longer ſtalk than the lateral ones. *Flowers* ſmall, numerous, pale red, in a pair of divaricated, ſtalked, axillary cluſters. *Capſule* ſhort, ovate.

Sect. 8. *Leaves fingered.* Six Species.

O. *lupiniſolia*. Lupine-leaved Wood Sorrel. Jacq. t. 72. Willd. n. 89. Ait. n. 55.—Stem none. Leaflets numerous, elliptic-lanceolate, glaucous, ſmooth. Stalks ſolitary, ſingle-flowered.—Native of the Cape.—The *leaves* ſpread like a fan; each leaflet has a black line at the baſe. *Flowers* large, of a golden yellow. This is a very handſome ſpecies, as well as Jacquin's *flava*, t. 73, which has narrow linear *leaflets*; *ſtabelliſolia*, t. 74, and *pectinata*, t. 75, both which laſt have broader oblong *leaflets*, and ſeem to us one ſpecies, differing merely in the comparative proportions of their *ſtamens* and *ſtyles*, like others already mentioned.

If we thus preſume to curtail the ſpecies, we do it with much reſpect for the able authors who have ſo greatly augmented the number, and we merely wiſh to ſuggeſt our ſcruples, which are altogether theoretical, for the conſideration of practical obſervers and cultivators.

Sect. 9. *Leaves pinnate.*

This ſection is at preſent known to contain only

O. *ſenſitiva*. Senſitive Pinnate Wood Sorrel. Linn. Sp. Pl. 622. Willd. n. 93. Jacq. t. 78. f. 4. (Herba ſentiens; Rumph. Amb. 301. t. 104. f. 2.)—Leaves pinnate.—Native of the Eaſt Indies; unknown in our gardens. The *ſtem* is ſhort and ſimple, crowned with a tuft of very numerous *leaves*, compoſed of many pair of obtuſe *leaflets*. *Flowers* yellow, in numerous ſtalked umbels. S.

Oxalis, in *Gardening*, contains plants of the hardy, herbaceous, perennial kind, of which the ſpecies cultivated are; the common wood ſorrel (O. acetoſella); the upright wood ſorrel (O. ſtricta); the goat's-foot wood ſorrel (O. caprina); the ſtriped-flowered wood ſorrel (O. verſicolor); the purple wood ſorrel (O. purpurea); and the fleſh-coloured wood ſorrel, (O. incarnata.)

But there are many other ſpecies that may be cultivated.

Method of Culture.—The firſt ſort may be readily increaſed, by planting the divided roots in a moiſt ſhady bor-

der

der in the early ſpring ſeaſon, which afterwards require only to be kept clear from weeds.

And the other ſorts may be increaſed, by planting off-ſets from the roots or bulbs that come out from the ſides of the ſtems, in pots filled with good light mould, ſheltering them in the dry ſtove or under a frame during the winter, admitting as much free air as poſſible in mild weather. They only require to be protected in the winter ſeaſon afterwards, and occaſionally removed into other pots.

The two firſt ſorts and varieties may be introduced in the borders, and the others afford variety among other potted plants.

Oxalis, in the *Materia Medica*. The oxalis aceto-toſella is totally inodorous, but has a grateful taſte, ſo that it is uſeful in ſallads by ſupplying the place of vinegar, and which is more agreeable than the common ſorrel, (rumex acetoſa,) and approaches nearly to that of the juice of lemon, or the acid of tartar, with which it alſo correſponds in a great meaſure in its medical effects, being eſteemed refrigerant, antiſcorbutic, and diuretic. It is recommended by Bergius in inflammatory, bilious, and putrid fevers. The principal uſe, however, of the acetoſella is to allay inordinate heat and to quench thirſt; for this purpoſe, a pleaſant whey may be formed by boiling the plant in milk, which, under certain circumſtances, may be preferable to the conſerve directed by the London College, though an extremely grateful and uſeful medicine. Many have employed the root of Lujula, probably on account of its beautiful red colour rather than for its ſuperior efficacy. An eſſential ſalt is prepared from this plant, known by the name of "eſſential ſalt of lemons," and commonly uſed for taking ink-ſtains out of linen. This ſalt is made from the expreſſed juice. Thunberg found that the oxalis cornua of the Cape of Good Hope yields the ſalt in greater quantity than the acetoſella. This ſalt, when genuine, which is ſeldom to be procured ſo, is compoſed of the vegetable alkali and a peculiar acid, which ſeems more allied to the acid of ſugar than that of tartar. Bergman has given the method of ſeparating this acid (Act. Up. Nov. vol. ii p. 215.), and it is related by Murray, Ap. Med. vol. iii. p. 497. What is ſold under the name of "eſſential ſalt of lemons" in this country, appears ſometimes to conſiſt of cream of tartar, with the addition of a ſmall quantity of vitriolic acid. The active principle of the expreſſed juice, which reddens vegetable blues, coagulates milk, and inſtantly precipitates lime from its ſolutions, is ſuperoxalat of potaſs, which is obtained cryſtallized from the juice, and ſold in the ſhops under the name of "eſſential ſalt of lemons." The ſame ſalt may be formed by cautiouſly dropping a ſolution of potaſs into a ſaturated ſolution of the oxalic acid, obtained from ſugar by the action of the nitric acid; the ſuperoxalat precipitates as ſoon as the proper quantity of alkali is added. On the continent this ſalt is prepared by the following proceſs: the juice is allowed to ſubſide after being ſlightly heated, and then clarified by adding to it water, in which a ſmall portion of fine clay is ſuſpended. This clarified juice is next boiled till a particle forms on its ſurface, and put aſide for a month to cryſtallize: the operation being repeated until the whole of the ſalt is obtained, when it is purified by a ſecond cryſtallization. Annal. de Chimie. xiv. 7. Woodville. Thomſon.

OXALME, in the *Materia Medica of the Ancients*, the name of a compoſition of vinegar and brine, made by a ſolution of ſea-ſalt in water. This was uſed externally in ulcers, and ſuppoſed of great ſervice againſt the bites of venomous animals, and for the curing children's ſcabby heads. It was alſo uſed as a ſtyptic poured into wounds, and was ſometimes given warm in clyſters; but theſe were always followed by thoſe of milk.

OX-BOOSE, in *Rural Economy*, a ſtall or place where oxen ſtand in the winter to be fed or fattened.

OXBOW, Great, in *Geography*, a bend of the river Connecticut, about the middle of the townſhip of Newbury, in Vermont; it contains 450 acres of the fineſt meadow land in New England.

OXELÆUM, a word uſed by many authors to expreſs a mixture of vinegar and oil, for outward application, in caſes of bruiſes and other injuries.

OXEN. See Ox.

Oxen *Creek*, in *Geography*, a river of Maryland, which runs into the Potomac, N. lat. 38° 55'. W. long. 37° 8'.

OXENBACH, a town of Auſtria; 9 miles S. of Ips.

OXENSTIERNA, Axel, *Count*, in *Biography*, a celebrated Swediſh miniſter, was born at Fano, in Upland, in 1583. He received his education at Roſtock, Wittenberg, and Jena, made great progreſs in the languages, and in various branches of ſcience, but he ſeemed particularly attached to theology. When he had finiſhed his academical ſtudies, he paid a viſit to moſt of the German courts; on his return he was received into the ſervice of Charles IX., who, in 1606, ſent him as envoy to the court of Mecklenburg. In 1609 he was admitted a member of the ſenate. The firſt public buſineſs aſſigned to him, was the adjuſtment of ſome differences that ſubſiſted between the Livonian nobility and the city of Revel, which he brought to a happy concluſion. He had now given ſuch a favourable diſplay of his talents, that the king, who was far advanced in life, made choice of him to be guardian to the royal family, and placed him at the head of the regency. On the acceſſion of Guſtavus Adolphus, he was promoted to be chancellor, and in 1613, when overtures were made for peace between Sweden and Denmark, he was appointed chief negociator on the part of the former. In the following year he accompanied the king in his expedition into Germany, and he had the ſatisfaction of ſeeing an end put to hoſtilities between Ruſſia and Sweden, by an honourable peace. He continued to advance in the confidence and eſteem of his ſovereign, till at length he was inveſted with full authority in all civil and military affairs on the Rhine, and the king having advanced into Bavaria and Franconia, Oxenſtierna fixed his head-quarters at Mentz, whence he proceeded with the troops that he had collected to join his majeſty, and then took up his ſtation with ſome regiments in the upper part of Germany, while Guſtavus advanced to Lutzen, where he fell in the arms of victory in the year 1632. Oxenſtierna was much afflicted, but not diſpirited, by this melancholy event. He collected more troops for the defence of Sweden and the allies; and undertook a journey to Dreſden and Berlin, to concert meaſures with the electors of Brandenburgh and Saxony, in regard to the proſecution of the war. An unlimited commiſſion was now given him by the Swediſh government, to purſue ſuch plans as he might think moſt conducive to the benefit of his country. He became director of the allied powers, diſtinguiſhed by the name of the Evangelic League. This elevation gave riſe to much diſcontent, and other circumſtances united with it threw things into confuſion. Oxenſtierna, however, by his prudent and judicious conduct, found means to revive the drooping ſpirits of his party, and to ſurmount every difficulty with which he was embarraſſed. He was recalled to Sweden in 1636, after an abſence of about ten years, reſigned the authority with which he had been inveſted, and took his ſeat in the ſenate as chancellor of the kingdom, and as one of the five guardians

dians of the queen. His chief care was now to inſtruct the queen in every thing that related to the art of government, and he had in a ſhort time the happineſs of being the means of concluding a peace by the famous treaty of Weſtphalia. He aſſiſted at Bromſebo at the negociation with Denmark in 1645, and on his return queeen Chriſtina conferred on him the title of count. At the ſame time he was choſen chancellor of the academy of Upſal, an office which he filled with zeal, aſſiduity, and ſucceſs. He oppoſed moſt earneſtly the intended abdication of the queen, and when he found his admonitions fruitleſs, he feigned indiſpoſition to avoid the mortification of being preſent at the debates on a meaſure which he conceived to be fraught with ſo much evil. He died in the month of Auguſt 1654, leaving behind him a great reputation for talents and diſintereſted virtues. "His character," ſays one of his biographers, "may be put in competition with that of the moſt celebrated men who have acted a diſtinguiſhed part on the grand theatre of the world; and his name will, at all times, be claſſed among thoſe who have done immortal honour to mankind. The natural powers of his mind were ſtrengthened by an excellent education, and by the ſtudy of the moſt uſeful ſciences. No perſon was better acquainted with the art of prying into the receſſes of the human heart; and the knowledge which he thus obtained he endeavoured to employ to the beſt advantage. His political ſagacity excited no leſs reſpect than admiration; and he lived at a period which gave him an opportunity of diſplaying, to its full extent, the ſtrength and ſolidity of his judgment. His eloquence was conciſe but nervous. He poſſeſſed the happy talent of foreſeeing the various reſults with which any meaſure might be attended, and of thence deducing the beſt rules for directing him in his public conduct. His integrity not only procured him friends, but enabled him to outſtrip all his competitors, and to overawe thoſe who were hoſtile to his deſigns. The ſtorms and vexations to which he was often expoſed, he withſtood with firmneſs, prudence, and magnanimity. The independence of his country was the darling object of his heart, and he poſſeſſed talents ſufficient to defend it againſt every attack. His name was celebrated all over Germany, and cardinal Richelieu was compelled to admit that his mind was an inexhauſtible ſource of wiſe counſels and prudent expedients." He was author of ſeveral works, of which a liſt is to be found in Stiernman's "Bibliotheca Suio-Gothica." The ſecond part of the "Hiſtoria Belli Sueco-Germanici," uſually aſcribed to P. B. Chemnitius, was compoſed by Oxenſtierna. Gen. Biog.

Oxenstierna, John, ſon of the preceding, was born at Stockholm in 1611. He was educated in a manner ſuitable to the rank of his family, and in 1631 he ſet out to improve himſelf ſtill farther by travelling in foreign countries. On his return he embraced a military life, and diſtinguiſhed himſelf ſo much by his zeal and activity in that department, that he was ſoon appointed colonel of a regiment in Germany. Being called by his father to Frankfort on the Mayne, to aſſiſt him in conducting the affairs of the evangelic league, he repaired to that city, and in 1634 was diſpatched thence to England on buſineſs of great importance. He was afterwards one of the commiſſioners for ſettling the affairs relating to Poland, and in 1641 was inveſted with full power as plenipotentiary to aſſiſt at the negociations for peace in Germany. Peace being concluded at Oſnaburg, Oxenſtierna was ordered by the queen to repair to Pomerania, to adjuſt ſome affairs with the elector of Brandenburgh; and on his return to Sweden he was appointed by Charles Guſtavus, who had then aſcended the throne, to be marſhal of the kingdom. In 1654 he was ſent again to Germany on public buſineſs, and died at Weimar, in December 1657. He was a man of great eloquence and extenſive knowledge. Whatever he undertook he exerted his utmoſt ability to accompliſh; and being guided in all his actions by a ſtrong ſenſe of rectitude, his conduct, on every occaſion, acquired for him eſteem and reſpect. Gen. Biog.

Oxenstierna, Eric, brother of the preceding, chancellor of Sweden, member of the ſenate, &c., was born at Fiholm, the ſeat of his family, in 1624. He ſtudied at Upſal, and in 1643 ſet out on a tour to Germany, with a view to improvement. On his return, queen Chriſtina appointed him firſt gentleman of the bed-chamber; but this office he reſigned in 1646, and was appointed governor of Eſthonia. He obtained other high offices in the ſtate, and was at length nominated vice-chancellor, in order that he might aſſiſt his father, now almoſt borne down by the weight of years and infirmity. After the diet of 1655, at which he proved by his talents that he was worthy of the confidence which placed him in that ſituation, he followed the king his maſter to Poland; and that country, as well as Pruſſia, having been reduced to the neceſſity of yielding to the Swediſh arms, Oxenſtierna was made choice of to conduct the negociations then entered into with the elector of Brandenburgh, which he brought to a happy termination. As a reward for this ſervice, he was raiſed by the king to be governor-general of Pruſſia, and this important office he retained till the period of his death, which took place at Elbing in 1656, when he was in the thirty-third year of his age.

OXEY, in *Rural Economy*, a provincial word, ſignifying like the ox, or of mature age, not ſteeriſh.

OX-FEET, a term applied to the feet of horſes, when the horn of the hind feet cleaves juſt in the middle of the forepart of the hoof, from the coronet to the ſhoe: they are not common, but very troubleſome, and often make a horſe halt.

OXFORD, in *Geography*, a city and univerſity of Great Britain, is ſeated nearly in the centre of England, on the ſouthern border of Oxfordſhire, to which it imparts a name, and is the chief or principal town of that county. This city occupies a ſcite which plainly indicates a monaſtic origin; and indeed ſtill retains many external features and internal cuſtoms expreſſive of its primary eſtabliſhment. It formerly contained nineteen monaſtic houſes. In natural poſition it has neither a military nor commercial aſpect; but is ſeated in a flat, ſedgy country, on a tract of land bounded eaſtward by the river Charwell, or Cherwell, and on the weſt by that of the Iſis. Theſe rivers ramify into numerous ſtreams at this place, and unite their accumulated waters on the ſouth ſide of the city. Both the rivers, as well as the city, have acquired claſſical celebrity by the harmonious ſtrains of different poets: Cowley, Pope, Prior, Phillips, Warton, and other modern authors, have attuned their reſpective lyres in praiſe of this "Modern Athens," as Camden ſtyles it. Wood, in "Athenæ Oxonienſes," mingling a little hyperbole with truth, pronounces Oxford "the moſt noble theatre, and emporium of all good ſciences, the very ſource and moſt clear ſpring of good literature and wiſdom; from which religion, civility, and learning have ſpread moſt plentifully through all parts of England, and beyond the ſeas." Many topographers and antiquaries have alſo evinced much labour and reſearch in developing the hiſtoric annals of the univerſity; but though ſeveral volumes have been appropriated to the ſubject, there is ample ſcope for a new work, to include all the eſſential information of former writers, with judicious criticiſm, antiquarian elucidation, and accurate illuſtration.

The appearance of Oxford from the high grounds to the eaſt and ſouth-weſt is ſingularly pictureſque and intereſting; it

it comprehends groups of towers, domes, ſpires, pinnacles, and turrets, intermixed with ſolemn maſſes of foliage; and ſurrounded by verdant meadows, interſected by ſeveral ſtreams. Occaſionally the latter preſent an ocean-like appearance; when the ſwoln waters overflow their natural bounds, and inundate the flat lands. At ſuch a time Oxford ſeems like an iſland; but it is an iſland filled with monaſtic palaces, intermixed with groves and gardens. In ſpring and autumn this effect is not unfrequent. The approaches to the city, from the eaſt, the London road, from the north, the weſt, and the ſouth, are all very impoſing and beautiful; and each preſents a very diſſimilar appearance and effect to either of the others. From the eaſt, Magdalen bridge, with the towers and groves of that college, and the rich botanic gardens, are ſeen near the fore-ground, over and beyond which the eye catches partial views of the towers and ſpires of St. Mary's, All-Saints, Chriſt-church, and other lofty buildings. On paſſing the bridge, and proceeding up the High-ſtreet, certainly one of the fineſt in Europe, the fronts of ſeveral colleges, churches, and private dwellings, are gradually and ſucceſſively unfolded to the ſight. This ſtreet is broad and long; it has a gentle bend or curve in its whole extent, and this conſtitutes one of its fine features. At almoſt every ſtep the paſſenger is preſented with new objects, and fine combinations; and at one point the whole coup d'œil is ſingularly impreſſive and pictureſque. This is at a broad part of the ſtreet, near the middle, where Queen's college, on the right hand, and Univerſity college, on the left, form the fore-ground of the ſcene, whilſt the front of All-Souls, the ſteeple and rich windows of St. Mary's church, the modern ſpire of All-Saints church, and the old tower of St. Martin's, conſtitute the prominent features in the diſtance; and all together preſent a ſtreet ſcene of unrivalled beauty, variety, and effect. This ſcene, heightened by the glow and brilliancy of the ſetting ſun, is rendered ſtill more impreſſive. (See a very fine print of it, 24 inches by 16, engraved by J. Pye, from a painting by J. M. W. Turner, R.A.) The other entrances to Oxford, though not ſo intereſting as this, are all grand, and highly prepoſſeſſing; and each is calculated to ſtimulate the curioſity of the ſtranger, and excite emotions of anxiety and pleaſure. A broad ſtreet, ſkirted with rows of old trees, and flanked by the obſervatory, St. Giles's church, St. John's college, and many private houſes, is the approach from the north; whilſt the oppoſite entrance is from meadows over three or four bridges, where the noble towers and turrets of Chriſt-church, with its vaſt grove of ſtately elms, conſtitute the chief feature. On the weſt the road is extremely unlike either of the former; and though not ſo grand and ſo architectural as thoſe, is ſingular and curious. An artificial cauſeway, or raiſed road, with ſeveral bridges over different branches of the Iſis, has been formed through the level meadows, for a full mile in length, and in nearly a ſtraight line. At the eaſtern termination of this, and at the weſtern extremity of the city, is a lofty conical mound, formerly the keep of the caſtle, with an ancient caſtle tower and ſome modern towers, which now conſtitute the county gaol.

The whole buildings of this city occupy an area of ground extending about one mile from north to ſouth, and the ſame length from eaſt to weſt. It is interſected in the ſame direction by two principal thoroughfares, or ſtreets, with ſeveral ſmaller ſtreets and lanes. On the ſouth, eaſt, and weſt, it is ſkirted by meadows, and on the north by corn fields. The latter ſide was formerly guarded by three different lines of fortification: a bold foſſe and ditch, at ſome diſtance from the buildings, extended from the river on the eaſt to the river on the weſt, and a lofty wall with baſtion towers, incloſed the chief buildings of the city on the ſame ſide. The city of Oxford, with its immediate ſuburbs and liberties, compriſes fourteen pariſhes.

In the following hiſtory and deſcription of this renowned ancient univerſity, but modern city, we propoſe to be more circumſtantial than in the generality of our topographical articles; becauſe, on examining other Cyclopædias, Gazetteers, and general geographical works, we find it has been very imperfectly and inaccurately treated. In the ſequel we ſhall particulariſe our authorities.

Hiſtorical Events.—As may be readily conjectured, the origin and ancient hiſtory of the town and univerſity have been ſubjects of anxious inveſtigation among the learned in different ages; and much curious, but fanciful ſpeculation, has been exhibited by thoſe who were ambitious to beſtow on it a claim to very remote antiquity. John Roſs, or Rous, whom Dugdale terms a "famous antiquary," even aſſerts, that a town was built here by Memphric, king of the Britons, upwards of a thouſand years before the Chriſtian era. This town, the ſame author obſerves, was firſt called Caer-Memphric, in honour of its founder; then Belleſitum, from a pretty mountain near it; afterwards Ridohen, implying, in the Celtic language, a ford of oxen; and Caer-Voſſei, from Boſſo; the name of an earl who was contemporary with king Arthur.

Such a view of the origin of Oxford, however, though accredited and repeated by ſeveral of the moſt diſtinguiſhed antiquaries of modern times, is juſtly conſidered by Camden and others to be fabulous, as the hiſtorian above quoted does not pretend to have derived his information on this ſubject, from any more authentic ſource than the legendary tales of the Britiſh bards. What ſtrongly corroborates their opinion is, the fact, that no mention of Oxford occurs during the Roman era; for the idea of Wood and Leland, that it was the *Calleva* of that celebrated people, and a place of ſplendour and notoriety under their government, has been proved to be altogether erroneous. The ſame doubts cloud the hiſtory of Oxford during the early part of the Saxon dynaſty, as at any former period. Indeed, no credit can be given, by the rational enquirer, to any ſtatement reſpecting it till the reign of Alfred, when it appears to have been famous for a monaſtery dedicated to the Holy Trinity. This was founded in 727, and was moſt probably the nucleus whence the town actually derived its origin, by collecting around it the habitations of the laity. At all events, whether this was the ſource of its exiſtence or not, it is certain that a town of ſome kind occupied the ſcite of Oxford in the tenth century. In 979 it was moſtly burnt, and in 1002 again ſuffered the ſame fate. It ſoon revived, however, but only to encounter freſh diſaſters. In 1009, Swein, king of Denmark, ſet fire to it; and when, in revenge, king Ethelred ordered a general maſſacre of the Danes throughout all his dominions, the command was executed with terrible fidelity at Oxford. No regard was paid either to ſex or age; even the altars were polluted with the blood of the devoted victims. Among thoſe who periſhed on this occaſion, was the lady Gunilda, ſiſter to the Daniſh monarch.

This ſavage policy of the Saxon king inflamed the reſentment of Swein to the higheſt pitch; he conſequently made a deſcent upon England with an overwhelming force, and laid in aſhes many of the principal towns; but it appears that he only frightened the inhabitants of Oxford into a ſurrender, and impoſed upon them a heavy contribution. About three years after this event, Ethelred having returned from France, whither he had fled to avoid the vengeance of Swein, invited ſome of the Daniſh nobles hither to a conference, and treacherouſly cauſed two of their number

number to be put to death. The remainder, fearing the ſame fate, immediately took to arms, but were overpowered; and either fell by the ſword, or were conſumed in the conflagration of St. Frid's church, in which ſome of them had ſought protection from the rage of their aſſailants. During the ſubſequent conteſts of the Danes and Saxons, Oxford frequently ſuffered ſeverely. It attained, however, at this period, a very high degree of political importance. King Edmund, ſurnamed Ironſide, occaſionally reſided here; and was unhappily murdered in the town, November 30th, 1016. Canute the Great held his court frequently at Oxford; and in 1022 he aſſembled here a general council, in which the laws of Edward were diſcuſſed, and made binding upon all his ſubjects, Danes as well as Engliſh. The ſame monarch, in a ſubſequent parliament, confirmed the edicts of king Edgar. Harold, ſurnamed Harefoot, likewiſe fixed his chief reſidence at this place, which was the ſcene both of his coronation and of his death. When William the Conqueror made a progreſs to the north, after he had been crowned at Weſtminſter, the inhabitants of Oxford being much attached to their deceaſed ſovereign, refuſed to open their gates to the uſurper of his throne. The king was therefore compelled to obtain entrance by force of arms; and as a puniſhment for their reſiſtance, he levied upon the townſmen a tax much higher than was paid by other towns. The better, however, to reſtrain their rebellious ſpirit, he conferred the government of Oxford on Robert de Oigli, a Norman of tried valour, and empowered him to build and fortify a caſtle. This ſtructure was of great ſize and ſtrength, and was raiſed on the weſt ſide of the town, near the river.

After the completion of the caſtle, Oxford became more ſubmiſſive, and long before the termination of the Conqueror's reign appears to have been perfectly reconciled to the Norman government. The immediate ſucceſſors of William frequently made it the place of their reſidence, and on ſeveral occaſions ſummoned parliaments and councils to it. When king William Rufus found his throne threatened by formidable inſurrections in the north, he convened a general council here, and declaring his reſolution to govern his ſubjects with ſtrict impartiality, ſucceeded in confirming the allegiance of many of his great barons, who might otherwiſe have deſerted his intereſt; and through their means was enabled to quell the revolt. King Stephen ſeveral times held his court here; and during the conteſt for the crown between him and the empreſs Maud, the latter having taken up her abode in the caſtle, was beſieged in it by the king in perſon, and only effected her eſcape, by ſtratagem, the day previous to its ſurrender. In 1154 a council met at Oxford, and it was formally agreed that Stephen ſhould retain the crown till his death, when it was to devolve on prince Henry, ſon to the empreſs.

Henry II. convened ſeveral councils at Oxford; and in the year 1177, the princes and chief lords of Wales did homage to him here for their territories and eſtates. This monarch reſided, during a great part of his reign, in the palace of Beaumont, which had been erected in the north ſuburbs by Henry I. Within the walls of that ſtructure, his heroic ſon, Richard Cour-de-Lion, was born, and ſubſequently held one council here anterior to his departure for the Holy Land. King John paſſed many of his troubled hours in the ſame palace; and had a meeting with his indignant barons in the vicinity about two months before he was compelled to ſign that grand bulwark of Engliſh liberty, Magna Charta. Henry III. following the example of his predeceſſors, occaſionally fixed his abode at Oxford, and held many parliaments and councils here on ſubjects of great political importance.

In the reign of Henry VIII. Oxford was conſtituted the ſeat of a biſhop's ſee, and conſequently elevated to the rank of a city. By order of queen Mary, archbiſhop Cranmer, with biſhops Ridley and Latimer, were executed here, October 1555, for hereſy to the Romiſh church. Her ſucceſſor, queen Elizabeth, frequently viſited Oxford, as will be more particularly mentioned in the ſequel of this article. In the year 1577 the plague raged with dreadful mortality in this town. While the court ſat on the trial of a popiſh bookſeller, accuſed of circulating offenſive pamphlets, a ſudden ſickneſs ſeized nearly the whole of the perſons preſent; and within forty hours upwards of 300 perſons died, among whom were the lord chief baron, the high ſheriff, ſeveral juſtices of the peace, and moſt of the jurors. The effect of the earthquake in 1580 was ſeverely felt at Oxford. The inhabitants quitted their houſes in great terror; but no very ſerious damage was done notwithſtanding the violence of the emotion. King James I. withdrew to this city when the plague broke out in London. The malady, however, likewiſe found its way hither, and began its devaſtations with ſuch awful effects, that the ſcholars fled from the univerſity, and the citizens ſhut their ſhops. "Not a living creature," ſays Ayliffe, "beſides nurſes and corpſe-bearers, was to be ſeen in the ſtreets, which were covered with graſs, even in the market-place."

Charles I. held a parliament at Oxford in the early part of his reign; and at a ſubſequent period, when he found it expedient to quit London, he choſe this city for his place of abode, being well aſſured of the loyalty of the citizens, and of the collegians. The whole melancholy winter of 1646 was ſpent by that monarch within the walls of Chriſt-church, where he aſſembled the ſhattered remains of his parliament, and whence he wrote the memorable letter to lord Digby, declaring, that "if he could not live as a king, he would die as a gentleman." The negociations for peace between Charles and the republican parliament were chiefly carried on at Oxford; but no military event of any conſequence occurred here throughout the war, though the city was ſtrongly fortified, and its poſſeſſion conſidered an object of great importance to both parties. It was ſurrendered by the expreſs command of the king himſelf, after he had been made priſoner by the Scots.

The laſt parliament which met at Oxford was convened in the year 1681, by king Charles II. As party ſpirit then prevailed in a very high degree, its meeting was attended with many boiſterous circumſtances. The popular faction affecting to dread ſome ſecret machinations among the Papiſts, their repreſentatives entered Oxford with a large train of ſervants and partizans as body guards. Numerous bands of ſoldiery were drawn up round the royal quarters; and on the whole, according to Hume, "the aſſembly rather bore the appearance of a tumultuous Poliſh diet than of a regular Engliſh parliament." This parliament laſted only ſeven days, having been diſſolved by the king to prevent a bill of baniſhment and excluſion from the throne being paſſed againſt his brother James, duke of York, afterwards James II., in whoſe reign many ſcenes of turbulence happened here, in conſequence of his illegal interference with the civil rights both of the city and univerſity. Since that time the annals of Oxford afford no very eminent hiſtorical particulars.

Origin and Hiſtory of the Univerſity.—The origin of the univerſity is no leſs involved in doubt and obſcurity than the early annals of the town. Indeed few circumſtances have occaſioned more zealous diſcuſſion than the comparative antiquity of this and the ſiſter univerſity of Cambridge. Numerous eſſays have been written on both ſides of the queſtion;

queſtion; in which much learning and curious inveſtigation have been diſplayed, but ſcarcely a ſentence of ſatisfactory information can be extracted from the voluminous maſs. Some of the more eager diſputants for the remote antiquity of Oxford contend that it was a ſeminary of learning immediately after the deſtruction of Troy. "The ſtudies of literature," obſerves Middendorp, "flouriſhed here ever ſince thoſe excellent philoſophers, with the Trojans, coming out of Greece, under the command of Brute, entered and ſettled in Britain." Other writers, leſs fantaſtical, wiſh to ſhew that the univerſity was founded by Arviragus, a Britiſh king, who lived in the time of Domitian, about ſeventy years ſubſequent to the Chriſtian era. A third claſs, with greater appearance of candour, decline to affix any preciſe date to its foundation, but uphold the opinion that it took place during the government of the Romans. All theſe notions, however, we are decidedly inclined to treat as chimerical, and unworthy of the ſmalleſt attention. We ſhall, therefore, paſs them over without further remark, and deſcend to a later period.

Among the many national improvements attributed to the great Alfred, the foundation, or, as ſome will have it, the reſtoration, of the univerſity of Oxford, is one of the moſt eminent. John Rous, the hiſtorian already mentioned, affirms, that he eſtabliſhed within this city, at his own expence, three teachers of grammar, arts, and divinity, in three different places. One of the fragments of Leland ſays, "Alfred founded the univerſity of Oxford at the inſtigation of his brother St. Neot;" and in the edition of Aſſer, the contemporary of the monarch, which was publiſhed by Camden in 1603, there are ſeveral paſſages corroborative of this aſſertion. The critical inquiries of ſucceeding writers, however, have clearly proved theſe paſſages to be interpolations, and to have formed no part of the genuine work of Aſſer. Many concluſive arguments have likewiſe been adduced to ſhew that Alfred never founded any ſchool eſtabliſhment, except that of Wincheſter. Whitaker, in his "Life of St. Neot," is particularly pointed in expoſing the abſurdities and contradictions by which the forgery is detected. The interpolated paragraphs do not appear in the older MS. publiſhed by archbiſhop Parker in 1574; nor in that in the Cottonian library ſince burnt, which Wanley dates about a century after Aſſer. Add to this, the fact that no mention is made of Alfred in the early ſtatutes, or other records of the univerſity, and it is not poſſible to reſiſt the conviction that Alfred had no concern either in its original foundation, or its revival at any ſubſequent period.

At what time then, it will perhaps be aſked, was the univerſity really founded? To this queſtion our anſwer is, that its progreſs to that rank was gradual, and that, in all probability, no regular ſyſtem of education, or corporate body for the purpoſes of learning, exiſted at Oxford till about the twelfth or thirteenth century. It is admitted, however, that there were numerous ſchools for the acquiſition of knowledge eſtabliſhed here at a much earlier date, but theſe were either of a private nature, or attached to ſome of the religious houſes with which the town abounded. The clergy, before the conqueſt, monopolized the ſmall portion of learning, which, in thoſe early days, was permitted to enliven the otherwiſe dark and cloudy atmoſphere of European ignorance. They were almoſt the only teachers to whom the people could apply for inſtruction. Every monaſtery, therefore, was in fact a ſchool; and whenever there chanced to be a number of them at one place, it might not improperly be called a ſeat of learning. It could not, however, be regarded in the light of an univerſity, as that term, in its modern ſignification at leaſt, implies a corporate eſtabliſhment, with the privileges of holding property and conferring degrees. In Domeſday-book no mention of ſuch a corporation occurs at Oxford.

Under this view of the ſubject it ſeems reaſonable to conclude, that when the Conqueror mounted the throne, Oxford enjoyed no greater pre-eminence in learning than what naturally reſulted from the number of its monaſtic eſtabliſhments, and from the circumſtance of its having been, during the preceding century, a favourite reſidence of the Engliſh monarchs. This, indeed, was a certain degree of diſtinction; and would aſſiſt in paving the way to the future celebrity of the town. Its ſchools might for theſe reaſons be more numerous, and better attended than in other towns, and might poſſibly poſſeſs ſome few trifling privileges, which would be gradually augmented, till the plan of a modern univerſity was completed.

Henry I., having been educated here, ſeems to have paid great attention to Oxford as a ſeminary for learning, and is ſaid to have granted to the teachers and the ſcholars ſome important privileges in their individual capacity. In the reign of Stephen learning ſunk to a very low ebb, and continued in the ſame degraded ſtate during that of his ſucceſſor Henry II. Richard I., however, ſtimulated its revival in every part of his dominions, but eſpecially gave encouragement to Oxford, becauſe of its having been the place of his birth. Many new halls or ſchools were eſtabliſhed under his royal patronage, and with money iſſued by his command from his own exchequer. To ſo flouriſhing a condition, indeed, did he raiſe Oxford, that the number of ſcholars at its ſeveral halls, in the early part of the ſucceeding reign, is ſtated to have been not leſs than three thouſand. But an unfortunate incident, in the year 1209, interrupted this courſe of proſperity, and even threatened the total deſtruction of the town, as a ſeat of knowledge. A ſtudent, engaged in ſome active exerciſe, accidentally killed a woman belonging to the town, and dreading puniſhment, was ſo imprudent as to fly from juſtice. The mayor and burgeſſes, upon being apprized of this occurrence, immediately ſurrounded the hall to which the ſuppoſed murderer belonged, and demanded his perſon. The maſter and ſcholars replied that he had fled; but this anſwer would not appeaſe the clamours of the multitude, who ſeized three ſtudents, entirely unconnected with the tranſaction, and obtaining an order from king John for their execution, hanged them without trial or proof. The teachers and ſcholars, juſtly enraged at this barbarous treatment, unanimouſly quitted Oxford, and retired, ſome to Cambridge, ſome to Reading, and ſome to Maidſtone in Kent. Nay, ſo far did they carry their revenge that they applied to the pope, and obtained a papal interdict againſt the town, and againſt all perſons who ſhould ſettle in it for the purpoſes of teaching. This meaſure effectually humbled the inhabitants, who ſoon after waited upon the pope's legate, and having begged pardon, and expreſſed the deepeſt contrition for their conduct, obtained abſolution upon conditions very favourable to the ſcholars. They conſequently returned to their ancient habitations, and the king himſelf beſtowed upon them ſeveral new immunities, and among others that they ſhould not be obliged to appear at any foreign judicature, "and that they might have cognizance in cauſes where one party is a ſcholar, or the ſervant of a ſcholar."

In the reign of Henry III., anno 1229, a ſerious diſpute having ariſen between the ſtudents and citizens of Paris, the king ſeized the opportunity to advance the intereſts of Oxford, by inviting the Pariſian maſters and ſcholars to ſettle there. Accordingly no fewer than one thouſand of them reſorted hither, but theſe foreigners introduced ſuch a

dangerous levity of manners, that tumults were continually breaking out, and cauſed great alarm and diſquiet in the town. They had ſometimes even the audacity to interfere in political matters. When prince Edward marched towards Wales, after his return from France, the burghers having forbid him entrance into the town, on account of the diſturbed ſtate of the realm, the ſcholars demanded to be let out to meet and ſalute him at his quarters without the walls. But this being denied by the bailiffs, they armed themſelves and broke open one of the gates, when a furious ſcuffle enſued, and terminated in the complete rout of the townſmen. In conſequence of this the king, who was on the eve of holding a parliament at Oxford, required the ſtudents to retire from the town until the parliamentary ſitting was concluded. The chief part of them therefore repaired to Northampton; and here they became implicated in a more ſerious affair than that which had occaſioned their removal. Offended at the king's command, which they regarded as a puniſhment, they joined the inſurgent barons in the defence of that town againſt the royal forces, and fought with ſuch deſperation, that the monarch would have proceeded againſt them with the utmoſt rigour after its ſurrender, had his vengeance not been reſtrained by prudential motives.

In ſuch circumſtances as we have deſcribed, it may reaſonably be ſuppoſed, that though the number of ſcholars during the reign of Henry III. was very great, yet the real votaries of learning were comparatively few. But ſtill amongſt theſe few ſome names have attained conſiderable diſtinction from their eminence in the faſhionable literature of the age, which was deeply corrupted with the ſubtleties of the Ariſtotelian philoſophy, and the myſteries of theological belief. The reign of Henry, however, will be always memorable in the annals of the univerſity, on account of an important acquiſition of private patronage which prevailed towards its concluſion. Previous to that period the teachers and ſcholars lodged, and ſtudied in manſions, or halls, rented from the townſmen; and this was one great ſource of the numerous quarrels which were conſtantly taking place between them. To remedy this evil, as well as to encourage learning, by conferring upon its profeſſors more complete independence than had hitherto been enjoyed, ſeveral public ſpirited individuals purchaſed, or built, large houſes for their reception, and ſet the example of appropriating funds for the ſupport of thoſe who might not poſſeſs the competent means of purſuing their ſtudies to advantage. By ſuch progreſſive ſteps a taſte for erecting and endowing colleges was introduced, and firſt modified, and at length ſupplanted that which had ſo long prevailed for the foundation of religious houſes, the nurſeries of ſuperſtition and ſcholaſtic ſophiſtry.

The reign of Edward I. is marked with no very intereſting features in the annals of literature. That prince, continually occupied in war, and in ſchemes of political aggrandizement, had little leiſure to attend to the advancement of learning. Some privileges, however, were conferred on the univerſity in his time; and towards the concluſion of his reign a violent diſpute aroſe between the univerſity, for ſuch the ſchool eſtabliſhments here had now really become, and the biſhop of Lincoln, in whoſe dioceſe Oxford was then included. This diſpute related to the limits of the biſhop's juriſdiction in univerſity matters, and ultimately led to the total emancipation of the learned body from eccleſiaſtical authority, under the ſanction of a papal bull, granted by pope Boniface in the year 1301.

Edward II. granted many additional privileges to the univerſity, and confirmed all the grants of his predeceſſors. Notwithſtanding this, however, party feuds were inceſſant, and occaſioned much retardation to the progreſs of learning. The preaching friars claiming the right of conferring degrees, independently of the univerſity, a violent conteſt aroſe on this point; and an appeal was made by both ſides to the pope, who, rather inclining to favour the friars, granted them an exemption from the chancellor's juriſdiction. But the king, at the interceſſion of the univerſity, decreed that this deed ſhould be held as void, and ordered that ſuch of the friars as refuſed to acknowledge the chancellor's authority within the precincts of the univerſity, ſhould be puniſhed with the utmoſt rigour. In this monarch's reign *lectures* were firſt inſtituted in the Hebrew language. The original lecturer, John de Briſtol, a converted Jew, is ſaid to have been a man of greater ſcience and erudition than was common in his age, and his lectures were received with the greateſt approbation.

Edward III. having been educated at Oxford, retained, during his whole life, a high veneration for the univerſity, and was more liberal in his grants to it, than any of his predeceſſors. Though almoſt conſtantly engaged in plans of ambition, the execution of which has afforded matter of wonder to ſucceeding ages, his vaſt and capacious mind did not forget the intereſts of literature. He effected many regulations in the police of the town, highly uſeful, and calculated to promote the health and comfort of the numerous ſtudents by which it was frequented. While he added progreſſively to the power of the ſuperior officers of the univerſity, he was equally careful to increaſe the conſequence and ſecurity of the ſcholars. He took the moſt decided meaſures to root out the ancient animoſity ariſing from difference of country as to north and ſouth, which had given birth to many dangerous tumults, and endeavoured to turn the current of jealouſy into the channel of emulation. The ſtate of ſociety, however, had not yet advanced far enough to teach men to reſtrain their ardour in debate within the bounds of decorum. The increaſe of learning augmented the violence of diſcuſſion on doctrinal points, and the univerſity became ſplit into ſects or parties, not one of which recollected that urbanity ſhould form the baſis of diſputation. Among the more celebrated of the diſputants at this period, were Duns Scotus, and Oakham. The former was the founder of the ſect called the Nominals, and the latter the patron of the Reals. The diſtinction between theſe ſects does not appear clearly upon record, but one ſubject of difference was the relative authority of the civil and eccleſiaſtical power. Oakham, who maintained the pre-eminence of the civil power, is ſaid even to have convinced the pope himſelf by the influence of his oratory. He was ſtyled by his holineſs the Invincible Doctor, and his antagoniſt the Subtile Doctor.

The plague, which occurred in 1349, nearly ruined the univerſity; all the colleges and halls having been deſerted and ſhut up during its prevalence. When its rage ceaſed, however, the ſcholars began to return, and by ſlow degrees their ſtudies were again reſumed. Durham college was founded ſhortly after this event, and king Edward, in order to reſtore the univerſity to its ancient ſplendour, confirmed all the former charters, and granted ſome new privileges.

The reign of Richard II. is diſtinguiſhed by the appearance at this univerſity, of one of the brighteſt luminaries that had hitherto enlightened the religious hemiſphere. We allude to Dr. John Wicliffe, a man whoſe name is yet deſervedly venerated by all who regard the reformation as an occurrence favourable to the intereſts of Chriſtianity, and to the progreſs of the human mind. This eminent character was the firſt warden of Canterbury college; and it was at Oxford that

that he read thoſe lectures on divinity which laid the baſis of the religious liberty we now enjoy. He looſened the ſhackles of papal thraldom which Henry VIII. afterwards burſt aſunder, though from motives of a very oppoſite nature to thoſe which animated the father of the reformers.

No ſooner were the doctrines of this great man divulged at Oxford, than they were approved of by the judicious, and received with enthuſiaſm by a large proportion of the univerſity. So ſtrong, indeed, was the ſentiment in their favour, that when pope Gregory ſeverely reproved the chancellor's neglect in ſuffering the hereſy to diffuſe itſelf, the proctors, and many of the maſters, heſitated much, whether they ſhould receive or reject the bull, as a new and unheard-of meaſure. (See WICLIFFE.) But though the ſpirit of the univerſity was thus favourable to liberty of opinion, learning was by no means in a flouriſhing condition at this era. The number of ſtudents had greatly diminiſhed; and many of the halls and ſchools were let for purpoſes entirely different from their original deſtination. Some new foundations, however, took place during this reign; but the ages which ſucceeded were dull and ſordid in a lamentable degree. The reigns of Henries IV. V. and VI. are only memorable for the violence of the religious diſſentions which prevailed, and had nearly produced a diſſolution of the univerſity. Henry VI. indeed, profeſſed much love towards Oxford; but his affection produced no ſolid benefit. The finances of the univerſity were low in his time, even to penury. Learning fell completely to decay, particularly that connected with the Latin language; and a general ſyſtem of bribery and corruption degraded the church. Benefices were diſpoſed of for intereſted conſiderations to perſons not in holy orders, while men of talent, and of long reſidence in the univerſity, were ſuffered to remain unnoticed in the ſecluſion of their reſpective colleges. Thus circumſtanced, the acceſſion of the houſe of York was viewed by many of the collegiates as a matter of indifference, and by ſome was even hailed with joy, from a hope that their ſituation might be bettered under the new dynaſty. Nor were they deceived in their expectations, for no ſooner was Edward IV. ſeated on the throne, than he aſſumed the title of "Protector of the Univerſity," and in many reſpects proved a zealous friend to the cauſe of learning. Richard III., who is commonly, but unjuſtly, ſtigmatized as the worſt of tyrants, was likewiſe a great benefactor to the univerſity, and an encourager of literature. Among many other judicious meaſures adopted by this monarch for its advancement, he paſſed a law, empowering the univerſity "to import or export books at pleaſure;" a permiſſion which may be rationally conſtrued to ſignify an entire freedom of the preſs, and liberty of diſcuſſion.

The reign of Henry VII. from a variety of fortuitous cauſes, is entitled to the proud diſtinction of having foſtered, with more than common ſucceſs, the revival of learning. From the many diſcouraging particulars of the preceding century, genuine ſcholarſhip had become almoſt an obſolete character, in a profeſſional light. The Greek language had not only fallen into general diſuſe, but was affectedly held in contempt, by a great body of the ſcholars, who formed themſelves into an aſſociation under the name of Trojans. So ſtrong, indeed, were the exiſting prejudices againſt this noble and harmonious language, that when Eraſmus repaired hither for the purpoſe of teaching Greek, ſeveral leading men in the univerſity read lectures againſt him in the ſchools, and endeavoured to attach ridicule both to the man, and to the knowledge which it was his object to diſſeminate.

The period during which Henry VIII. held the ſceptre, is, in ſome reſpects, one of the brighteſt in the annals of the univerſity. Soon after his acceſſion, this prince confirmed all the grants of his predeceſſors, and honoured Oxford with a regal viſit. Wolſey, ſo celebrated for his unexpected elevation to the higheſt pinnacle of power, for his talents, and for his fall, proved himſelf one of the moſt munificent patrons of learning that graced his own or any other age. In 1518 this illuſtrious prelate and ſtateſman founded ſeven lectures for theology, civil law, phyſic, philoſophy, mathematics, Greek, and rhetoric, and appointed to all ſuch men as were moſt diſtinguiſhed for their abilities and for their knowledge in theſe reſpective branches of learning. His efforts to promote the good of the univerſity were indeed vigorous and uniform. Through his means the Greek language was again received into eſtimation, and a taſte for elegant literature was introduced, and this happily ſupplanted the quibbling ſophiſtry which had hitherto occupied the chief attention of the learned. Wolſey alſo founded the college, now called Chriſt-church. About the ſame time the colleges of Brazennoſe and Corpus Chriſti were alſo founded, the former by Wm. Smyth, biſhop of Lincoln, and ſir Robert Sutton, and the latter by Richard Fox, biſhop of Wincheſter.

Two events of a political nature happened in this reign, which may not improperly claim ſome notice in an hiſtorical ſketch of the univerſity. The firſt was the divorce of queen Catharine of Arragon, on the legality of which the king thought proper to conſult the Oxonians; and with ſome difficulty ſucceeded in obtaining an anſwer favourable to his wiſhes. The ſecond related to his intention of declaring himſelf "Head of the Church," on which ſubject he likewiſe took the ſenſe of this univerſity, and was confirmed in his purpoſe by their almoſt unanimous vote. It was ſoon perceived, however, that his object in this meaſure was not freedom from foreign domination, but the ſpoliation of the church, and, therefore, their acquieſcence in his views was naturally at an end. The univerſity now preſented a moſt diſmal ſpectacle. The plague, together with the calamities of the church, concurred in driving the ſtudents from their habitations, and ſo few in number were thoſe who reſorted hither at this era, that in the year 1546, only ten inceptors in arts, and three in divinity and law, are recorded.

The acceſſion of Edward VI. brought with it evils of no leſs magnitude than thoſe which marked the footſteps of his father. The firſt act of this young prince's counſellors, (for to them muſt belong the merit or demerit of almoſt every act of his reign,) was a groſs infringement on the rights and privileges of the univerſity, as it directed, "that no gownſmen ſhould concern themſelves at the election of any preſident, fellow, or ſcholar, or do any thing to oppoſe the viſitation now ordered by the king." Accordingly, when the threatened viſitation took place, the royal commiſſioners executed whatever meaſures they deemed proper. They entirely changed the form of the univerſity government, and framed a new code of ſtatutes, called Edward's ſtatutes, which remained in force until archbiſhop Laud introduced a better model. They, moreover, deſpoiled the libraries, and deſtroyed many rare manuſcripts on ſubjects of ſcience, merely becauſe they had been written by votaries of the old ſchool. This treatment ſo inflamed the few remaining ſcholars, that the greater part of them quitted Oxford, and retired to foreign ſeminaries to proſecute their ſtudies.

When queen Mary aſcended the throne, the ancient forms and government were again eſtabliſhed, and the late regulations completely abrogated. The popiſh party, now in their turn predominant, was not behind its antagoniſts in the work of cruelty and deſtruction. The ingenious arts were conſigned to contempt; the divinity ſchool was ſeldom opened; for which reaſon the ſtipend of queen Margaret's lecture was converted to the uſe of repairing the ſchools; there

was ſcarcely one ſermon preached in the city in a month; public lectures were neglected, either through inſufficiency or idleneſs. The Greek tongue again fell into almoſt total diſuſe, and, in general, learning, in every branch, was ſunk to the loweſt ebb. For ſix years there were only three inceptors in divinity, eleven in civil law, and ſix in phyſic. Of maſters of arts there were during one year only eighteen, another nineteen, another twenty-five, and another twenty-ſeven, in the whole univerſity.

The death of Mary, without iſſue, gave Elizabeth poſſeſſion of the regal ſceptre at a moſt critical juncture for the united intereſts of religion, as well as of learning. This wiſe and politic princeſs reverſed all that her ſiſter had effected in the conſtitution of the univerſity. But, unlike her predeceſſors, ſhe conducted the change with gentleneſs and moderation. Objectionable individuals were ſimply deprived of their places, or induced to reſign, and no greater puniſhment than a few days impriſonment was inflicted, even upon the obſtinate oppoſers of the queen's meaſures. Theſe, however, were ſome time before they produced the deſired effect of reſtoring the univerſity to any tolerable degree of proſperity. The ſhock occaſioned by the verſatile ſtate of the court-religion, during the three previous reigns, and the conſequent uncertainty of eccleſiaſtical proviſion, was not to be quickly overcome. In the year 1560, not one perſon performed theological exerciſes in the ſchools, and only one in civil law, and three in phyſic. No divine, legiſt, or phyſician, ſtood that year for a degree. In 1563 there were only three univerſity preachers in Oxford, and two of theſe ſhortly afterwards retired. Hence the pulpit was frequently ſupplied by laymen. Mr. Taverner, ſheriff of Oxfordſhire, mounted the pulpit, with his ſword by his ſide, and his golden chain of office round his neck, and preached a ſermon to the academics. This event ſufficiently evinces that the condition of eccleſiaſtical literature muſt have been low indeed, or the Oxonians never could have liſtened to ſuch flagrant abſurdity as the following. "Arriving at the mount of St. Mary's," ſays this preacher at the commencement of his ſermon, "in the ſtony ſtage where I now ſtand, I have brought you ſome fine biſcuits baked in the oven of charity, carefully conſerved for the chickens of the church, the ſparrows of the ſpirit, and the ſweet ſwallows of ſalvation."

In the 13th year of queen Elizabeth the two univerſities were incorporated by act of parliament; and two years ſubſequent, the obligation of ſubſcribing the articles of the church of England began to be rigidly enforced on all who entered into the miniſtry. This occaſioned conſiderable diſturbance, as there were many perſons in the univerſity who favoured the puritanical doctrines, and peremptorily refuſed their aſſent to the propoſed articles. The chancellor (the earl of Leiceſter) was ſtrongly tinctured with Calviniſtic ſentiments; and ſir Francis Walſingham, the queen's ſecretary, was notoriouſly a partiſan of the Puritans. Hence ſectarian principles unavoidably gained ground; but notwithſtanding the univerſity rapidly roſe in conſequence, and could boaſt among its members numerous individuals eminent for their proficiency in almoſt every branch of the liberal arts or ſciences. Queen Elizabeth twice viſited the univerſity, and on one of theſe occaſions delivered a Latin ſpeech, extempore, with ſo much eaſe and correctneſs, as excited the ſurpriſe of all who heard her. (See Nichols' Account of "Queen Elizabeth's Progreſſes.") In this reign ſir Thomas Bodley founded the Bodleian library, which has proved an highly uſeful and valuable addition to the univerſity.

The reign of James I. is remarkable in the annals of the univerſity for the privilege it then acquired of ſending two repreſentatives to the national council. In this era, the diſputes between the Papiſts, Epiſcopalians, and Puritans, were carried to a great height, and proved highly injurious to the intereſts of ſolid learning, by inducing too eager a thirſt for controverſial inquiry. On this account ſir Henry Savile informs us, "that geometry was almoſt totally unknown and abandoned;" and hence we may fairly preſume that many of the other ſciences were in a ſimilar ſtate of decay and neglect.

Charles I., in the early part of his reign, conferred ſome important benefits on the univerſity. At the interceſſion of the chancellor, the celebrated archbiſhop Laud, he granted to it a new charter, in which its ancient liberties and privileges were explained and confirmed; and new ones were added. This charter was ſealed with the great ſeal of England, and to diſtinguiſh it from other grants, it was denominated the *Caroline charter*. In 1636, the ſtatutes of the univerſity, after being corrected and enlarged, and approved of by the heads of the colleges, received the royal ſanction; and in 1638 the ſtatute, ordering the examination of all candidates for degrees, was firſt put in execution. During the rebellion, which broke out ſhortly after, the univerſity maintained an inviolable allegiance to the unfortunate monarch; and even when the parliament maſtered the kingdom, and commiſſioners were deputed to reform the diſcipline, and correct the erroneous doctrines of the univerſity by the rule of covenant, the great majority of its members met in convocation, and paſſed a public act and declaration againſt the proffered opinions. "An act," obſerves lord Clarendon, "which muſt remain to the world's end, as a monument of the learning, courage, and loyalty of this excellent place."

But the firmneſs of the univerſity was of little avail in checking the religious fanaticiſm which at this period poſſeſſed the minds of the predominant party. The dean and chapter's lands were ſold; the Epiſcopalian divines were ejected; the libraries were pillaged; and ſome of the more zealous votaries even proceeded ſo far as to deſtroy the ornaments and decorations of the ſeveral colleges, without regard to the circumſtance whether they bore relation to matters of religion, or not. Claſſical learning now experienced a total ſtagnation. The candidates for holy orders were no longer required to be men of ſcience and polite erudition: it was enough if they "abounded in grace," and were "endowed with the ſpirit of preaching." Still, amidſt this melancholy ſcene of religious bigotry, a few men of real talent inhabited the more ſhady receſſes of the univerſity, and kept alive the dying embers of genuine knowledge. Theſe individuals met together at ſtated periods, to communicate to each other their reſpective diſcoveries in phyſics and geometry; and thus laid the foundation of the Royal Society, the moſt honourable and ſcientific inſtitution of which our country can boaſt. Cromwell, who was elected chancellor of Oxford in 1650, gave ſeveral proofs of his predilection for learning, but the temper of the times is ſuppoſed to have checked his efforts for its revival and encouragement. On the reſtoration, however, this ſentiment being in a great meaſure removed, the univerſity was again replaced on its former baſis. The lands of the dean and chapter were reſtored, and moſt of the perſons who had ſuffered expulſion on account of their principles, were reinſtated in their reſpective collegiate ſtations. Learning once more began to flouriſh, and ſome of thoſe who were the proudeſt boaſts of ſcience and of literature matured their ſtudies, or laid the foundation of their future eminence here, in the reign of the ſecond Charles.

But this pleaſing aſpect of affairs did not continue long; violent party contentions diſturbed the peace of the univerſity

ſity during the whole reign of James II., who exhibited a ſignal proof of his determination to ſubvert the civil and religious liberties of the country, in his conduct towards Magdalen college. It happened that ſhortly after he had aſcended the throne, the preſident of that eſtabliſhment died; and the king tranſmitted an order for the election of a perſon named Farmer as ſucceſſor in that office. The fellows, however, knowing that this Farmer was a man of contemptible character, petitioned his majeſty either to leave them the freedom of choice which their ſtatutes entitled them to aſſume, or to propoſe a more reſpectable individual for their head. James took no notice of this application, ſo that when the day of election arrived, the fellows elected Dr. Hough for preſident. This meaſure rouſed the vengeance of the monarch, who ſent down an inferior eccleſiaſtical commiſſion, the perſons entruſted with which conſented to withdraw Farmer, upon condition that Parker, then lately created biſhop of Oxford, ſhould be choſen in his ſtead. But this prelate being likewiſe a man of low character, and ſtrongly inclined to popery, the collegiates firmly adhered to their original election, and urged the tenor of their ſtatutes in defence of their reſolution. Their arguments, however, had little weight with the king, who viewed their refuſal to obey his mandate as an act bordering on rebellion. He therefore repaired to Oxford in perſon, and commanded the fellows to appear before him at Chriſt-church; but finding that even his own preſence could not influence their deciſion, he expelled the whole of them, except two, from the college. This conduct of the monarch excited the deteſtation of all friends to cool reaſon and upright government; and in 1688, when James became alarmed by the preparations of the prince of Orange to invade his dominions, one of the firſt meaſures he adopted to conciliate his ſubjects, was the re-inſtatement of the expelled members of Magdalen college.

From the period of the revolution to the preſent day, the univerſity of Oxford has continued to flouriſh in an unexampled degree. Its revenues have been increaſed, and the ſyſtem of education has generally kept pace with the improvements which have happily been accompliſhed in almoſt every branch of human ſcience. The doctrines of the ſchools, indeed, were received and taught here for ſome time after they had been exploded in the northern univerſities, but they have now yielded, as in other ſeminaries, to the more rational views of the experimental philoſophy. For ſome remarks on the ſtate of national learning during the laſt century, and the peculiar features of univerſity tuition, diſcipline, and influence, ſee UNIVERSITY.

Preſent State of the Univerſity, its Officers, &c.—The univerſity, as a corporate body, has been governed by ſtatutes enacted at different periods, and ſanctioned by charters granted in different reigns. Thoſe at preſent in force were chiefly drawn up in 1620, and were confirmed, as already mentioned, by king Charles I. in the year 1635. In that charter the corporation is ſtyled "The Chancellor, Maſters, and Scholars of the Univerſity of Oxford," and this body is veſted with the power of framing laws for its own government.

The principal officers of the univerſity are, the chancellor; the high ſteward; the vice chancellor; two proctors; a public orator; a keeper of the archives; a regiſtrar; numerous public lecturers and profeſſors; two curators of the theatre; two clerks of the market; the Bodleian librarian, and the keeper of the Aſhmolean muſeum. The firſt five mentioned officers are inveſted with magiſterial authority, and have the power of appointing deputies.

The *Chancellor* is choſen by the members of convocation, and now holds his office for life, though formerly it was annual, or at moſt triennial. It is a ſtation of great dignity, and is uſually filled by a perſon of the firſt eminence in the kingdom. The duties of the chancellor are to ſuperintend the intereſts of the univerſity, to defend its privileges, and to decide, either in perſon, or by deputy, in all civil queſtions in which a member happens to be involved. For this purpoſe he is empowered to hold regular courts; he likewiſe preſides, if preſent, at all univerſity meetings, and poſſeſſes an abſolute negative on their proceedings. The preſent chancellor is the right honourable lord Grenville, who was elected in the year 1809.

The *High-Steward* is nominated by the chancellor, but muſt be approved of by convocation. He holds his office for life, and is bound to aſſiſt the chancellor, vice-chancellor, and proctors, in the execution of their ſeveral duties, and to ſit in judgment in capital cauſes, where a member of the univerſity, or a privileged perſon, is the party offending. He likewiſe holds the univerſity court-leet either in perſon or by deputy. Lord Eldon, lord high chancellor of Great Britain, the preſent high ſteward, was elected in 1801.

The *Vice-Chancellor*, who is always the head of ſome college, is appointed by the chancellor, and admitted, and ſworn, in convocation. This office is annual, but the ſame individual is uſually named for four ſucceſſive years. The vice-chancellor nominates four deputies, or pro-vice-chancellors, who muſt likewiſe be heads of colleges. His duties are to enforce the univerſity regulations, to call congregations, convocations, and courts, licenſe taverns, expel delinquents, &c. The preſent vice-chancellor is John Cole, D.D. rector of Exeter college, appointed in 1810.

The *Proctors* are maſters of arts of at leaſt four years ſtanding, and not more than ten from their regency. They are elected by the common ſuffrage of all doctors and maſters of arts in their reſpective colleges, according to a cycle ordained in the Caroline ſtatutes, and have each the right of appointing a deputy. Their buſineſs is to aſſiſt the vice-chancellor in convocations and congregations; to ſuperintend the ſcholaſtic exerciſes, to enforce the ſtatutes, and to preſerve the public peace. Their names in 1812, were Charles Wightwick, and Thomas Davies.

The *Public Orator* is choſen by convocation, and muſt either be a bachelor of civil law or a maſter of arts. He is the ſecretary, or organ of the univerſity, writes letters and addreſſes on public occaſions, and delivers the annual Crewian oration alternately with the profeſſor of poetry. He likewiſe preſents the honorary degree of M.A. to thoſe on whom it may be conferred. The Rev. Wm. Crowe is the preſent public orator.

The *Keeper of the Archives* is elected by convocation, and is entruſted with the care and arrangement of all records and charters belonging to the univerſity, and on certain occaſions is appointed to defend its rights and privileges. This office is now veſted in Whittington Landon, D.D. provoſt of Worceſter college.

The *Regiſtrar* attends all univerſity meetings, and regiſters all its acts; ſuch as diſpenſations, graces, &c.; takes copies of all letters ſent or received, and collects the univerſity rents. This officer muſt be M.A. or B.C.L. and notary public. The Rev. John Gutch, M.A. the continuator of Wood's hiſtory, &c. of Oxford, has long held this reſpectable office.

The *Profeſſors* and *Lecturers* are public officers, who have certain ſalaries allowed to them, on ſome foundation, and who are, in conſequence, required to deliver lectures annually, on ſuch ſubjects as the founders may have appointed in their charters, or wills. The lectureſhips at preſent in Oxford are twenty-five in number, and are as follows.

The

The Regius profeſſorſhips of divinity, civil law, medicine, Hebrew, and Greek, founded, about the year 1535, by Henry VIII. and endowed by him with a yearly revenue of 40*l.* each, which has ſince been augmented by additional endowments.

The Margaret profeſſorſhip of divinity, founded by Margaret, counteſs of Richmond, mother of Henry VII., in 1497.

The profeſſorſhip of natural philoſophy, founded by the executors of ſir William Sedley, of Aylesford, in Kent, who left 20,000*l.* by will, for that purpoſe.

The Savilian profeſſorſhips of geometry and aſtronomy, founded, in 1619, by ſir Henry Savile, knt. Theſe profeſſorſhips are open to men of every nation.

The Camden profeſſorſhip of ancient hiſtory, founded by William Camden, Clarencieux king at Arms, in 1622. It is ſingular that our valuable chorographer did not inſtitute a profeſſorſhip of topography or antiquities.

The anatomical lecture, founded by Richard Tomlins, A.D. 1623, is annexed to the Regius profeſſorſhip of medicine.

The profeſſorſhip of muſic, founded in 1626, by William Heather, Muſ. Doct.

The Laudian profeſſorſhip of Arabic, founded and endowed by archbiſhop Laud, in 1636.

The profeſſorſhips of botany, one of which was founded by D. W. Sherard in 1728, and the other by his preſent majeſty, in 1793. The botanic garden was founded by the earl of Danby, in 1632.

The profeſſorſhip of poetry, founded by Dr. Henry Birkhead, in 1708.

The Regius profeſſorſhip of modern hiſtory and modern languages, founded by George I. in 1724.

The Anglo-Saxon profeſſorſhip, founded by Richard Rawlinſon, LL.D. in 1750, though the endowment did not take effect till 1795, as ordered by his will, dated June 2, 1752.

The Vinerian profeſſorſhip of common law, founded, in 1758, by the univerſity, in conformity to the will of Charles Viner, eſq. who bequeathed 12.000*l.* for that purpoſe. The celebrated ſir William Blackſtone was the firſt profeſſor on this foundation, and gave it high diſtinction by his admirable "Commentaries," which were firſt read here, and have ſince paſſed through ſeveral editions.

The Clinical profeſſorſhip, founded in 1772, with funds left by the earl of Lichfield, then chancellor of the univerſity. The lectures are delivered in the Radcliffe infirmary.

The lord almoner's reader, who is paid out of the almonry bounty.

The Aldrichian profeſſorſhip of anatomy, of the practice of medicine, and of chemiſtry, founded in 1803, under the will of Dr. Aldrich. The firſt is annexed to the prælectorſhip of anatomy.

The Bampton lectures on certain ſubjects in divinity, founded by John Bampton, M. A., canon of Saliſbury, in 1780. The office is annual, and the ſame perſon cannot officiate twice.

The *Curators of the Theatre* are two officers appointed by convocation to take charge of the building ſo called, in which the public meetings of the univerſity are held on great occaſions.

The *Clerks of the Markets* were inſtituted for the better care and government of the market. Their duty is to regulate the aſſiſe of bread, to obſerve the weights and meaſures, the prices and quality of proviſion, and to fine foreſtallers, regraters, &c.

The *Bodleian Librarian* is elected by convocation, and the office muſt be ſupplied within three days after it has become vacant, except during the long vacation, when three weeks are allowed. The Rev. John Price has inherited this office for 44 years.

The *Keeper of the Aſhmolean Muſeum* is appointed by the viſitors of that curious repoſitory. This office was endowed with a ſalary by Dr. Rawlinſon, with the ſingular reſtrictions, "that the keeper ſhould be a layman, of the degree of M.A. or B.C.L. only, unmarried, and neither F.R.S., nor F.S.A."

The whole buſineſs of the univerſity, in its corporate capacity, is conducted in two ſeparate aſſemblies, called the "Houſe of Congregation," and the "Houſe of Convocation."

The *Houſe of Congregation* is conſtituted entirely of regents; either of neceſſary regents, or regents *ad placitum*. Of theſe, nine at leaſt, beſides the vice-chancellor and proctors, are required to make a congregation. The buſineſs of this aſſembly refers chiefly to the paſſing of graces and diſpenſations, and to the granting of degrees. All votes are given ſecretly, by whiſper in the ear of the proctor; and in the inſtance of ſupplicating for graces, every member has a ſuſpending negative in three ſucceſſive congregations.

The *Houſe of Convocation*, which is compoſed of regents and non-regents alike, but with certain limitations, is privileged to inveſtigate and determine every ſubject, in which the intereſt of the univerſity is concerned. In this aſſembly, laws are enacted, altered, or explained, without reſtriction, unleſs the ſtatute propoſed to be altered be a Caroline ſtatute, and then the royal conſent muſt be previouſly obtained. In both theſe meetings, the chancellor or vice-chancellor ſingly, and the two proctors jointly, are officially empowered to negative every proceeding. All queſtions are decided by a majority of votes; and all elections, except for members of parliament, are conducted by a private ſcrutiny in writing.

The *Hebdomadal Meeting* is a ſort of committee or council to both houſes, and conſiſts of the vice-chancellor, heads of colleges and halls, and proctors, who are empowered to deliberate on all matters relating to the privileges, ſtatutes, and cuſtoms of the univerſity, and report on them in convocation, or congregation.

The ſeveral *degrees* conferred by the univerſity of Oxford are thoſe of doctors of divinity, civil law, medicine, and muſic; of bachelors in theſe ſciences, and of maſters and bachelors of arts. For the attainment of each of theſe degrees, a reſidence for a certain number of terms is required See DEGREE.

Colleges and Halls.—Having thus given a general view of the univerſity and of its officers, we proceed to notice its ſeveral foundations ſeparately. Of theſe, twenty are diſtinct, endowed corporations, and are termed colleges; and five are halls, or buildings appropriated for the reſidence of ſtudents, under the ſuperintendence of a principal, who receives rent for their chambers. The following is a liſt of theſe inſtitutions, according to the date of their reſpective charters of foundation.

Colleges.

1.	Merton College, founded -	A.D. 1264
2.	Univerſity College - - -	1280
3.	Balliol College - - -	1281
4.	Exeter College - - - -	1314
5.	Oriel College - - - -	1326
6.	Queen's College - - - -	1340
7.	New	

7.	New College, founded	A.D. 1386
8.	Lincoln College	1427
9.	All-Souls College	1437
10.	Magdalen College	1456
11.	The King's Hall and College of Braſen-Noſe	1509
12.	Corpus Chriſti College	1516
13.	Chriſt-Church	1525
14.	Trinity College	1554
15.	St. John's College	1557
16.	Jeſus College	1571
17.	Wadham College	1613
18.	Pembroke College	1620
19.	Worceſter College	1714
20.	Hertford College	1740

Halls.

1.	St. Alban's Hall, about	1200
2.	Edmund Hall	1317
3.	St. Mary's Hall	1325
4.	New Inn Hall	1391
5.	St. Mary Magdalen Hall	1480

Merton College, which is the oldeſt in point of legal eſtabliſhment in the univerſity, was founded by Walter de Merton, biſhop of Rocheſter, and lord chancellor of England, who began to erect the buildings about the year 1260, and eſtabliſhed the college by charter, dated January 7, 1264, under the appellation of "Domus Scholiarum de Merton." A ſecond charter was granted in 1270, and a third in 1274; both confirming the original deed, and adding new privileges and poſſeſſions to thoſe previouſly conferred. The firſt officers of this college were nominated in 1276, about two years after the completion of the buildings. Its chief benefactors, beſides the founder, were Ella, counteſs of Warwick, about the year 1295; John Willyott, chancellor of Exeter, in 1380; Dr. Thomas Jeſſop, phyſician, in 1595; William Rede, biſhop of Chicheſter; and ſir Thomas Bodley. This college is ſituated in St. John's ſtreet, to the eaſt of Corpus Chriſti, and its buildings are arranged round three courts or quadrangles. The outer court to the ſtreet was rebuilt in 1589, with the exception of the tower and gate-houſe, which were conſtructed in the early part of the 15th century, in the wardenſhip of Thomas Rodburne, biſhop of St. David's, and one of the moſt diſtinguiſhed mathematicians of his age. Within this court are the warden's lodgings, ſome portions of which are ſuppoſed to be coeval with the original edifice. The ſecond or grand court is of modern date, and exhibits a mixed ſtyle of architecture: the centre elevation is adorned with four tiers of columns, or four orders of architecture; but the third or ſmall court is of ancient erection, and is ſuppoſed to have been entirely built about the ſame time with the library, which forms its ſouth and weſt ſides. This library was founded in 1376, by the biſhop of Chicheſter above mentioned, and is the oldeſt ſtructure, diſtinctly appropriated as ſuch, in the kingdom. In 1550, whe the work of reformation was conducted, in ſome inſtances, with more zeal than judgment, many of the printed books and MSS. belonging to this inſtitution were either ſold or deſtroyed. Upon the reſtoration of the library, however, by ſir Thomas Bodley, a conſiderable part of them was recovered by the liberality of thoſe private individuals by whom they had been purchaſed. The hall of this college is remarkable, as having been the room in which queen Elizabeth was entertained at dinner, on the occaſion of her viſit to the univerſity, with her privy council, in 1592.

The number of ſtudents at Merton college has varied at different periods, and appears to have been regulated by the changes which occurred in its revenue. In 1612, the ſociety conſiſted of ninety-three members, but at preſent there are only forty-eight; a warden, twenty-four fellows, two chaplains, fourteen poſt-maſters, four ſcholars, and two clerks. The warden is choſen from among the fellows, who preſent a leet of three to the archbiſhop of Canterbury, by whom one of them is appointed to the office. The firſt common room, uſed in any college in Great Britain, was fitted up here in 1661. Among the more eminent members of Merton college were Duns Scotus, Wicliffe, ſir Henry Savile, Dr. Harvey, the diſcoverer of the circulation of the blood, the celebrated Druſius, and Robert Devereux, earl of Eſſex, the parliamentary general, whoſe character is ſo ingenuouſly drawn by lord Clarendon.

Univerſity College, as already noticed, is ſaid to have owed its origin to king Alfred. Smith, in his hiſtory of this college, has proved to the ſatisfaction of every unprejudiced mind, that it was founded by the univerſity, with the money of William of Durham, who died at Rouen in Normandy, in the year 1249, and bequeathed 310 marks to purchaſe certain annual rents for the maintenance of ten, eleven, twelve, or more maſters. At firſt, the funds left by this benefactor were appropriated to the ſupport of a limited number of individuals, (choſen from the various halls of the univerſity,) who did not form an independent ſociety, but were ſeverally ſubordinate to the ſchools in which they had been educated. In 1280, however, they were conſtituted a ſociety by themſelves, under certain conditions; and in 1292, their privileges were confirmed and enlarged by a body of ſtatutes. The ſituation of their houſe, or hall, at this period, is uncertain; but hiſtorians have generally placed it on part of the ſcite of Brazen-noſe college, and aſſert that they removed to the preſent college, in the High-ſtreet, about the year 1343. On this removal, they ſtyled themſelves the Maſters and Scholars of the Hall of the Univerſity of Oxford, and their houſe Univerſity-hall; but in 1381, the latter began to be called Great Univerſity-hall. When the term college was firſt applied is not aſcertained, nor is it known at what time the corporation was completed. This, however, moſt probably did not take place till about the year 1475, when the body of ſtatutes, ſtill in force, were enacted; but a common ſeal was uſed as early as the year 1320.

Numerous benefactors to this college appeared within the firſt century after its foundation; and in 1403 Walter Shirlaw, biſhop of Durham, gave the manor of Mark's-hall, in Eſſex, for the maintenance of three fellows, natives of York and Durham. Henry, earl of Northumberland, in 1442, gave lands and the advowſon of a rectory to ſupport three bachelors or maſters of arts from the dioceſes of Durham, Carliſle, and York. In 1566, Joan Davys, wife of a citizen of Oxford, gave certain eſtates for the eſtabliſhment of two logic lecturers, or one in logic and another in philoſophy; and for an augmentation of the allowance to the maſters and fellows. Francis Ruſſel, ſecond earl of Bedford, Robert Dudley, earl of Leiceſter, John Freyſton of Altofts in Yorkſhire, the Rev. Robert Gunſley, and ſir Simon Bennet, were likewiſe very conſiderable donors. But the greateſt benefactor of modern times was Dr. Radcliffe, who, beſides rendering munificent aſſiſtance toward improving the buildings of the college, inſtituted and endowed two travelling fellowſhips for ſtudents in medicine. Each fellow receives 300*l.* *per annum* for ten years, the firſt five of which he is required to ſpend abroad.

Univerſity college ſtands on the ſouth ſide of High-ſtreet, and conſiſts principally of two quadrangular courts, one of which

which was built at various times between the years 1634 and 1675. It is one hundred feet ſquare, with a chapel and hall on the ſouth ſide. The other court, which was chiefly erected by Dr. Radcliffe, has only three ſides, the fourth opening to the maſter's garden. Theſe two quadrangles form a grand front towards the ſtreet, of about 260 feet in length, with two tower gateways. The chapel of this college was built in 1665, and diſplays much painted glaſs in the windows. It alſo contains a cenotaph to the memory of ſir William Jones, the celebrated orientaliſt, which was deſigned and executed by John Flaxman, R.A., and is highly creditable to the talents of the artiſt. The bas-relief is ſurmounted by tigers' heads, and repreſents the lamented ſubject of the funeral trophy engaged in a digeſt of the Hindu code, with Brahmins in attendance. The library here was completed in 1669, and is furniſhed with a very valuable collection of books and MSS.

Balliol college owes its foundation to John de Balliol, of Bernard's caſtle, in the county of Durham, father to the unfortunate king of Scotland of the ſame name. This gentleman, who poſſeſſed a taſte for literature, and a benevolence of diſpoſition little prevalent in the thirteenth century, commenced it in the year 1263, and intended that it ſhould maintain ſixteen poor ſcholars of Oxford. He died, however, without having effected the deſign, and ſo ſuddenly that he left no will, but verbally enjoined his lady and executors to take charge of and give permanency to his infant inſtitution. Lady Dervorgille accordingly, at the inſtigation of her confeſſor Richard Slickbury, hired a houſe on the ſcite of the preſent college; and was ſo fortunate as to meet with the concurrence of the founder's executors in all her ſubſequent ſteps to perpetuate the eſtabliſhment. In 1282 ſhe appointed ſtatutes under her ſeal, which are intereſting, becauſe they ſerve to throw ſome light on the modes of collegiate diſcipline at that early period. In 1284 the lady Dervorgille purchaſed a tenement called Mary's-hall, and having repaired and enlarged it, transferred the ſcholars to this new reſidence, which was henceforth called New Balliol college. The ſame year ſhe preſented them with ſome lands in the county of Northumberland, and had their ſtatutes confirmed by Oliver, biſhop of Lincoln, and by her ſon John de Balliol, who at that time held the Scottiſh ſceptre under the protection of Edward I. But notwithſtanding theſe generous efforts, the revenues of the college ſtill continued extremely ſmall, not yielding above eight-pence *per* week to each ſcholar. A number of benefactors, however, ſoon aroſe, and by their united contributions conferred a conſiderable degree of opulence on the inſtitution. In 1294, Hugh de Wychenbroke gave the advowſon of St. Lawrence, Old-Jewry, London; and in 1310 Hugh de Warkenby, and William de Gotham, gave four meſſuages, in School-ſtreet, for the ſupport of a chaplain to officiate in the oratory. In 1320, Richard de Hunſinſore alſo gave a tenement in Oxford; but theſe donations were trivial compared with the liberal gifts of ſir William Fenton, and ſir Philip Somervyle. The benefaction of the latter, indeed, was deemed ſo conſiderable as to entitle him to the honours of a ſecond founder. A new body of ſtatutes was drawn out under his ſanction, one article of which enacted, that the ſociety ſhould henceforward be governed by a maſter. Theſe ſtatutes were confirmed by Edward Balliol, king of Scotland, and remained in force till 1364, when a third code was enacted by Simon de Sudbury, afterwards archbiſhop of Canterbury. In 1507 this code was likewiſe ſuperſeded, and the one at preſent in force ſubſtituted in its ſtead. Among the various benefactors ſince that period, the moſt diſtinguiſhed were Thomas Harrope, rector of Haſely; Peter Blundell of Tiverton in Devonſhire; lady Elizabeth Periam of Greenland, in Berkſhire, ſiſter to the great lord Bacon; Dr. John Warner, biſhop of Rocheſter; and John Snell of Warwickſhire. The two laſt gave donations excluſively for the benefit of Scotch ſcholars.

As in Merton college, the members of this ſociety have varied in number at different periods, according to the ſtate of its finances. In 1612 the ſociety conſiſted of one hundred and twenty-ſeven perſons, but at preſent the number is reduced to a maſter, twelve fellows, fourteen ſcholars, and eighteen exhibitioners. The viſitor is elected by the college, which is the only one in the univerſity that enjoys a like privilege. John Wicliffe, the celebrated reformer, was one of the maſters of this college.

The buildings of Balliol college were erected at various times on the ſcite of the tenements or halls hired and purchaſed by the lady Dervorgille, and are chiefly arranged round a quadrangle, which is 120 feet long and 80 broad, in the interior. The front towards the ſtreet preſents much irregularity of ſtructure. Over the entrance, in the centre, is a fine ſquare tower, embattled at the top, with an oriel window in front, alſo a highly enriched and canopied niche on each ſide. This gateway is likewiſe adorned with the arms of Balliol. The buildings to the eaſt and weſt of the tower were conſtructed at the beginning of the laſt century, and poſſeſs little conſonance of character with the older portions of the college. Within the court the ſame diſſimilarity of architecture is viſible as on the outſide. The hall, and the reſidence of the maſter, occupy its weſtern ſide; the northern ſide is compoſed of the chapel and library, and the other ſides are appropriated as lodgings for the fellows and ſcholars. The library was built in two parts, that towards the weſt by Dr. Chace, A.D. 1427, and that on the eaſt by Robert Abdy in 1477. The interior of the whole has been lately renewed under the ſuperintendence of James Wyatt, architect. Formerly this library was eſteemed among the firſt in the univerſity. Before the time of Edward VI. it was particularly rich in MSS., above two hundred of which, highly illuminated, were preſented by Grey, biſhop of Ely, in 1454. Moſt of theſe, however, have been ſince loſt or deſtroyed, but the collection of printed books is ſtill both valuable and extenſive.

Beſides the quadrangle, there is an area on the north-weſt, conſiſting of ſeveral detached lodgings for the ſtudents. Theſe were purchaſed and made over to the ſociety by archbiſhop Abbot. There is likewiſe a building belonging to the college, at the ſouth-weſt angle of the quadrangle fronting the ſtreet. It was erected at the expence of Mr. Fiſher, late fellow of Balliol.

Exeter college was founded in the year 1315, by Walter de Stapleton, biſhop of Exeter, who was likewiſe the founder of Hert or Hart hall, now Hertford college, the origin of which is ſo intimately blended with that of Exeter college, that it is difficult, at leaſt for ſome time, to conſider them as ſeparate eſtabliſhments. The rector and ſcholars of Hart hall, indeed, were actually the firſt poſſeſſors of this college, having been removed to the buildings which formerly occupied the preſent ſcite, and others dependent on them ſubſtituted in their ſtead. According to the ſtatutes then formed, the ſociety was to conſiſt of thirteen members, eight of whom were to be choſen from Devonſhire, four from Cornwall, and one, a prieſt, nominated by the dean and chapter of Exeter, from any part of the kingdom. The chief benefactors of this inſtitution were Edmund Stafford, biſhop of Exeter, who added two fellowſhips, and reformed the ſtatutes in 1404; and ſir William Petre, who procured a new body of ſtatutes, and a regular deed of incorporation for

for the college in 1565. The ſame gentleman likewiſe endowed eight new fellowſhips. The other conſiderable contributors to the proſperity of this eſtabliſhment, were ſir John Ackland; king Charles I.; ſir John Maynard; Samuel Hill, rector of Warlegan; and the lady Shiers. In 1612, the ſociety of Exeter college conſiſted of 206 perſons. The preſent members are a rector, twenty-five fellows, one ſcholar, who is bible clerk, and ten exhibitioners, beſides other ſtudents. The biſhop of Exeter is viſitor.

The buildings of this college encompaſs a ſingle quadrangle. The grand entrance facing the ſtreet is ſurmounted by a tower with Ionic pilaſters, which ſupports a ſemicircular pediment, ornamented with the arms of the founder on a ſhield ſurrounded with feſtoons. The inner front is of ſimilar conſtruction; but the arms here are thoſe of lord Petre. More uniformity prevails in the architecture of this college than in any of thoſe hitherto noticed; and, on the whole, its appearance is ſimple and pleaſing. The chapel, which occupies a large portion of one ſide, is a neat and ſolid edifice in the later pointed ſtyle, and poſſeſſes the peculiarity of having two aiſles. The hall is a handſome building, alſo in the pointed ſtyle, erected by ſir John Ackland about the year 1620; but the library is of modern erection, and contains, among other valuable works, a fine collection of Aldine claſſics.

Oriel College was founded, about the year 1324, by Adam de Brom, rector of St. Mary's in Oxford, under the ſanction of Edward II., to whom he afterwards ſurrendered the whole, in the hope of obtaining the royal protection for his infant eſtabliſhment. Nor were his expectations groundleſs, for the king readily took the college under his eſpecial care, and the next year granted a new charter, appointing it a college for divinity and the canon law, to be governed by a provoſt. He likewiſe beſtowed upon the ſociety ſome tenements in Oxford, and the advowſon of St. Mary's church, on condition of their providing chaplains for the daily ſervice. Adam de Brom was named the firſt provoſt, and drew up a code of ſtatutes in 1326, by which the college was to conſiſt of a provoſt, ten fellows or ſcholars, ſeven to ſtudy divinity, and three the canon law. He likewiſe gave them the livings of Aberforth in Yorkſhire, and Coleby in Lincolnſhire; and in 1327 Edward III. beſtowed upon them a large meſſuage called La Oriole, or Oriel, to which the members ſoon after removed; and hence the college derived its preſent name. The chief ſubſequent benefactors of this inſtitution were John Franke, lord chancellor of England in 1441; Carpenter, biſhop of Worceſter; Smyth, biſhop of Lincoln; Dr. Richard Dudley, chancellor of Sarum; Dr. Robinſon, biſhop of London; Dr. Carter, provoſt of the college in 1708; Charles, fourth duke of Beaufort, and her majeſty queen Anne. By ſome of theſe benefactors fellowſhips were founded, ſo that the ſociety now conſiſts of a provoſt, eighteen fellows, fifteen exhibitioners, and other ſtudents. The lord chancellor is the viſitor.

The buildings conſiſt of a large quadrangle, and two lateral ranges of chambers for the reception of ſtudents, with a library between. The whole of the quadrangle was rebuilt in the early part of the 17th century, and both exteriorly and interiorly poſſeſſes uniformity of ſtyle and conſtruction. The front, towards the ſtreet, is divided by a ſquare tower, which riſes over the entrance, and is ornamented with a bay window or oriel. The hall faces the gateway, and is approached by a flight of ſteps under a portico, ſurmounted by ſtatues of Edward II. and III. in niches, with the virgin and child in another niche, immediately above. The provoſt's lodgings are on the north ſide; and the buildings on the ſouth and weſt are entirely appropriated for the accommodation of ſtudents. The library was deſigned by James Wyatt, eſq. architect, and executed under his direction. It contains, among many other books, a very curious and valuable collection, which was bequeathed to the ſociety by Edward, lord Leigh of Stourleigh.

Queen's College was founded by Robert Eglesfeld, confeſſor to queen Philippa, the illuſtrious conſort of Edward III. The founder was deſcended from an honourable family in the county of Cumberland, and appears to have been deſervedly held in high eſtimation by his royal maſter and miſtreſs, as he employed his intereſt at court chiefly in promoting religion and learning. Anxious to ſupply the means of education to the border counties, in which, to uſe his own expreſſions, "an unuſual ſcarcity of literature prevailed," he purchaſed ſome tenements on or near the ſcite of the preſent buildings, and obtained a charter, dated January 18, 1340, from Edward III., to conſtitute a collegiate hall under the name of "Aula Scholarium Reginæ de Oxon." a title which ſeems to imply that the queen had ſome ſhare in its inſtitution. At all events, ſhe took it immediately after under her protection, and, in conſequence, the honorary patronage of the college has ever ſince appertained to the queens of England. By the original charter and ſtatutes of this eſtabliſhment, the ſociety was to conſiſt of a provoſt and twelve fellows or ſcholars; the provoſt to be in holy orders, and choſen from among the fellows, who were to be natives of Cumberland and Weſtmorland, in the firſt inſtance; and afterwards of thoſe counties in which the college poſſeſſed property. This number, however, has ſince been increaſed by various benefactions, but by none ſo much as by that of John Michel, eſq. of Richmond, who bequeathed to Queen's college eſtates valued at 700*l.* a-year, for the maintenance of eight maſter fellows, four bachelor ſcholars, and four under-graduate ſcholars, or exhibitioners; and for the erection of ſuitable buildings for the accommodation of the maſters and ſcholars; ſo that this has been conſidered in the light of a new foundation. The queens who have contributed to the college, beſides queen Philippa, are Henrietta Maria, conſort to Charles I., the late queen Caroline, and her preſent majeſty. The firſt gave three rectories and as many vicarages, and the two laſt preſented 1000*l.* each towards enlarging and repairing the buildings, which now conſiſt of two courts, divided by the hall and chapel, and forming an oblong 300 feet long and 220 broad. With the exception of the chapel, the whole of this college was erected during the laſt century. The ſtyle of its architecture is, therefore, modern. The principal front is in the High-ſtreet, and has in the centre a large gateway, over which is a ſtatue of queen Caroline, under a cupola ſupported by pillars. This gateway leads into the firſt court, which bears, in general, a remarkable reſemblance to the Luxembourg palace at Paris. It was executed by Hawkſmoor, from a deſign either by ſir Chriſtopher Wren, or by Dr. Lancaſter. The principal library-room is one of the largeſt in the univerſity, and is arranged in a very taſteful manner. Here are two very ancient paintings on glaſs of Henry V., who received his education at this college.

New College is indebted for its origin to William de Wykeham, biſhop of Wincheſter, one of the moſt illuſtrious characters of his age. This prelate was born in 1324, and roſe through ſucceſſive gradations to the higheſt offices of the ſtate, and to the greateſt influence in the church. (See WYKEHAM). He originally founded the ſociety of New college about the year 1373, and eſtabliſhed the members in halls, which he hired for their reception, till a college could

be erected. Of this college he laid the foundation-ſtone in 1380, under the authority of the king's licence, and likewiſe of the pope's bull; but the buildings were not completed for a period of ſix years. As ſoon as they were, however, the ſociety was removed into them, and took poſſeſſion with great ſolemnity. The ſame year, biſhop Wykeham began his collegiate eſtabliſhment at Wincheſter, which was to ſerve as a nurſery to that of Oxford, ſo grand and comprehenſive was the original deſign of this diſtinguiſhed benefactor. Both ſocieties, by their reſpective charters and ſtatutes, were made to conſiſt of a warden and ſeventy ſcholars, beſides prieſts, clerks, and choriſters, for the ſervice of the chapels. That of Wincheſter had likewiſe a ſchoolmaſter and uſher, and was to ſupply ſtudents to the Oxford college, by election, and to ſubmit to an annual viſitation from the warden and two fellows of the latter. Many ſpecial privileges were at this time ſecured to New college, of which one was, that the fellows ſhould be admitted to all degrees in the univerſity, upon being found qualified by examinations conducted, according to form, in their own college. This right was queſtioned in 1608, but decided by the then chancellor, archbiſhop Bancroft, in favour of Wykeham's foundation.

Many benefactors have contributed to augment the proſperity of this college beſides the founder, but only one appeared during his life-time. This was John de Buckingham, biſhop of Lincoln, who preſented to the ſociety the advowſon of Swalcliffe church, together with ſome adjacent lands. Of the ſubſequent donors, the principal were Thomas Beckington, biſhop of Bath; Robert Shireburn, biſhop of Chicheſter; John Smyth, a burgher of Ipſwich; Dr. Fleſhmonger, dean of Chicheſter; and Chriſtopher Rawlins, vicar of Alderbury in 1589. By the aſſiſtance of theſe, and numerous ſmaller benefactions, this ſociety became one of the richeſt in Oxford, its yearly revenues being reckoned at 1000*l.* in 1592, when it conſiſted of one hundred and thirty perſons. The preſent members are a warden, ſeventy fellows, ten chaplains, three clerks, a ſexton, and ſixteen choriſters. The whole of the fellows muſt be elected from Wincheſter, at a regular meeting for that purpoſe, which is attended by the wardens of both colleges, two fellows of New college, and the ſubwarden and head maſter of Wincheſter. The viſitor of New college is the biſhop of Wincheſter. In the original charter of foundation, this college is entitled "Seinte Marie College of Wyncheſtre;" but having popularly received the name of New college at the time of its erection, it has, by a remarkable inattention to propriety, retained that appellation through every ſucceeding age.

The buildings of this college are extenſive, diverſified, and intereſting. As originally projected by the founder, they conſiſted of a ſpacious quadrangle, including the chapel, hall and library, with a ſmall quadrangle adjoining, called the cloiſters. The other buildings which form the garden court conſtitute an addition to the original deſign, and were built in 1684, in imitation either of the palace of Verſailles, or of the king's houſe at Wincheſter. The approach to the great quadrangle is by a portal, with a tower above, which ſtill retains the ſculptured effigy of Wykeham in one of its ornamented niches. The chapel and hall on the north ſide of the great court preſent as fine an elevation as any in the univerſity. The former is peculiarly beautiful and chaſte in its interior decorations. The choir of this ſtructure is 100 feet long, 35 broad, and 65 high; and the anti-chapel, running at right angles into the choir, meaſures about 80 feet in length by 36 in breadth. The windows of the latter diviſion afford a magnificent diſplay of painted glaſs, in four different ſtyles of execution. None of them, however, come near, either with reſpect to deſign or beauty of colouring, to the great weſt window, which probably equals any ſimilar effort in the pictorial art in Great Britain. It was executed by Jervais from finiſhed cartoons by ſir Joſhua Reynolds, and is divided into two parts, the higher repreſenting the Nativity, and the lower ſeven figures emblematic of the Chriſtian and cardinal virtues. The famous crozier of the founder is preſerved in this chapel: and over the altar table are ſome beautiful ſpecimens of ſculpture from the chiſſel of Richard Weſtmacott, eſq. R.A.

Lincoln College.—The original inſtitution of this college took place in 1427, when Richard Flemming, biſhop of Lincoln, obtained the royal licence to eſtabliſh a ſociety of one rector or warden, ſeven fellows, and two chaplains in the church of All-Saints, Oxford, and to unite to that church thoſe of St. Mildred and St. Michael, under the general name of the firſt. This ſociety he appointed perpetual parſons of the collegiate church, and intended to have erected buildings for the reception of its members, but was prevented by death from executing his benevolent views. They continued to reſide, therefore, in a tenement called Deep-hall, till the original deſign of the preſent college was completed by the munificent exertions of biſhop Rotheram, who was afterwards archbiſhop of York. This prelate likewiſe increaſed the number of fellows from ſeven to twelve, and framed a body of ſtatutes for the government of the ſociety. Various other benefactors have ariſen ſince that period, among whom biſhop Smyth, the founder of Brazen-Noſe, Edward Darby, M.A. archdeacon of Stow, and Nathaniel, lord Crew, biſhop of Durham, were the principal; the ſociety now conſiſts of a rector, twelve fellows, eight ſcholars, twelve exhibitioners, and a bible clerk. The biſhop of Lincoln is viſitor.

The chief buildings of this college compoſe two quadrangular courts. The firſt court, began ſoon after the founder's death, and finiſhed by biſhop Rotheram, ſtill retains much of the character of ancient collegiate ſtructures. It contains the hall, the library, the rector's lodgings, the common room, and ſome apartments for ſcholars, all of which are of low elevation, and arranged with great ſimplicity. The other quadrangle was erected about the year 1612, with the exception of ſix ſets of rooms, which were added in 1759. The chief ornament of this court is the chapel, built at the expence of Dr. John Williams, biſhop of Lincoln.

All-Souls College was founded, in the year 1437, by Henry Chichele, archbiſhop of Canterbury, who prevailed on king Henry VI. to aſſume the title of co-founder. Chichele, however, retained all legiſlative power reſpecting the new eſtabliſhment, and drew up a code of ſtatutes, after the model of thoſe promulgated by biſhop Wykeham. By theſe ſtatutes, in conformity with the charter, the ſociety was made to conſiſt of a warden and twenty fellows, of whom ſixteen were to ſtudy the civil and canon laws, and the remainder philoſophy, and the arts, and divinity. Chaplains, clerks, and choriſters were likewiſe added for the ſervice of the chapel. Numerous benefactors have enriched this college at different periods, by whoſe conjunct donations the ſociety has been enabled to augment the number of its members to a warden, forty fellows, two chaplains, and ſix clerks and choriſters. The warden is elected in the ſame manner as the warden of Merton college. The archbiſhop of Canterbury is viſitor.

The buildings of this college conſtitute two large quadrangles, one of which is entered from High-ſtreet, and the other from Radcliffe-ſquare. The former was erected by the founder, and though in ſome parts modernized, ſtill preſerves

ſerves many features of the original ſtyle of its architecture. Two niches over the principal entrance contain large and well-ſculptured ſtatues of king Edward VI. and of Chichele. The latter quadrangle is comparatively of modern erection, and meaſures, within the court, 172 feet in length, and 155 in breadth. On the weſt are the grand entrance and the cloiſter; on the eaſt the common room and other apartments, with two handſome towers; on the ſouth the chapel and hall; and on the north the library. "This quadrangle," ſays Chalmers, "eſpecially when viewed from the weſt entrance, preſents one of the moſt attractive ſcenes of which Oxford can boaſt. The general ſtyle is the mixed Gothic." The library, which was begun in 1716, and only completed in 1756, owes its erection to the munificence of colonel Coddrington, who left 10,000*l.* for that purpoſe, beſides bequeathing to the ſociety a collection of books, then valued at upwards of 6000*l.* The principal room is probably the largeſt ſo appropriated in the kingdom, being 198 feet in length, and 32½ in breadth, excluſive of a grand central receſs, in the area of which is fixed a ſtatue of the colonel. Dr. Young, author of the Night Thoughts, laid the foundation ſtone of this ſtructure, which was deſigned by Hawkſmoor, and chiefly executed under his direction.

Magdalen College was founded by William of Waynflete, biſhop of Wincheſter, under the authority of a licence, dated July 18, 1457, for a preſident, forty fellows, thirty ſcholars called *demies*, a divinity lecturer, a ſchool-maſter, an uſher, four chaplains, an organiſt, eight clerks, and ſixteen choriſters. The fellows were directed to ſtudy divinity, medicine, and the canon law, and the demies to be "converſant in grammar, logic, ſophiſtry, and that ſpecies of muſic called plain ſong, or chaunting." Among the chief benefactors of this inſtitution were ſir John Faſtolf, who appointed the founder one of his executors, William, earl of Arundel, Ralph Freman, and John Norris, LL.D. by whoſe, and other donations, added to the endowments of Waynflete, the college became ſo opulent, that its annual revenues were eſtimated, in 1535, at 1076*l.* 5*s.* 2*d.* The members of this ſociety ſtill remain the ſame in number as at the time of foundation, with the addition only of gentlemen commoners, for no commoners are admitted. The biſhop of Wincheſter is viſitor.

The buildings of this college, as deſigned by the founder, compoſe two quadrangular courts, one of ſmall, and another of large dimenſions. The entrance to the firſt is through a modern portal of the Doric order, which appears very inappropriate, and very badly accords with the reſt of the ſtructure. This court contains the preſident's lodgings on the left, and in front is the entrance door-way to the chapel. This door-way is a very curious and beautiful ſpecimen of architecture. In niches over it are ſmall ſtatues of Waynflete, Henry VI., St. John the Baptiſt, and St. Mary Magdalen, ſtanding in canopies of exquiſite workmanſhip. The large quadrangle remains nearly in the ſame ſtate in which the founder left it, the ſouth cloiſter being the only portion of the buildings that has been added ſince his death. Here are the chapel, hall, and library, a part of the preſident's lodgings, and chambers for the fellows and demies. The chapel, a moſt elegant ſtructure, contains numerous monuments of perſons connected with the college, and has its windows highly ornamented with painted glaſs. Round the whole interior of this court is ranged a ſeries of large hieroglyphic figures, which have afforded matter of much enquiry among the Oxford topographers.

Beſides the two courts above-mentioned there are a tower, and ſeveral other ranges of buildings belonging to Magdalen college, which have been erected at different periods, and were not included in Waynflete's deſign. The tower is a ſtructure of very fine proportion, and is ſuppoſed to have been deſigned by the celebrated Wolſey, while he was burſar of this college. It was commenced in 1492, and finiſhed in 1498. A few years afterwards the chaplain's court was built; and ſome further rooms, towards the eaſt, were added in 1635. At the beginning of the laſt century, a plan was propoſed, and agreed to, for the building of a new quadrangle, but only one ſide of it has yet been finiſhed. By this plan, three ſides of the old quadrangle were to have been demoliſhed, leaving only the hall, chapel, and ſouth cloiſter.

Magdalen college being bound by its ſtatutes to entertain the kings of England and their ſons when at Oxford, the hall has frequently been the ſcene of royal and princely feſtivity. Edward IV., and Richard III., were both entertained here by the founder. In 1496, prince Arthur paid a viſit to this college, and in 1605 James I. held his court within its walls, upon which occaſion Henry, prince of Wales, was admitted a member of the ſociety. Oliver Cromwell, Fairfax, and other principal officers of the parliamentary army, alſo had a ſumptuous dinner provided for them here in 1649, and afterwards played at bowls in the college green, which, with the grove and water walk, form pleaſure-grounds of great extent and beauty.

Brazen-Noſe College.—This noble inſtitution was founded by William Smyth, biſhop of Lincoln, in concert with his friend ſir Richard Sutton. The buildings were began about the year 1509, and ſhortly after the ſociety was formed and accommodated in ſome of the ancient premiſes, which occupied the ſite of the preſent college, and moſt probably in the tenement called Brazen-Noſe hall, whence the new foundation derived its name. By the charter of incorporation, which is dated 15th of January, 1511-12, this ſociety was to conſiſt of a principal and ſixty ſcholars; but in 1621, a reviſion of the ſtatutes having been made by the ſurviving founder, ſir Robert Sutton, the members were limited to a principal and twelve fellows. They were ſoon, however, augmented by the munificence of ſucceeding benefactors, ſome of whom added fellowſhips, others ſcholarſhips and exhibitions, others lectureſhips in philoſophy, in humanity, Hebrew, Greek, and mathematics. Theſe laſt were founded by ſir John Port, John Barneſton, D.D., Richard Harper, a judge of the common pleas, and Thomas Weſton, rector of Criſſelton, near Cheſter. The other contributors are too numerous to be mentioned; ſo that we ſhall only obſerve, that by their conjunct donations, the ſociety now conſiſts of a principal, twenty fellows, thirty-two ſcholars, and fifteen exhibitioners, beſides a great number of independent members. The biſhop of Lincoln is viſitor.

The buildings of this college are arranged round a large quadrangle and a ſmaller court to the ſouth, with the exception of the reſidence of the principal, and lodgings for ſeven ſtudents, which are detached. The large quadrangle contains the hall and chambers for the ſociety; and has ſuffered little alteration ſince it was originally built, except the addition of a continued attic. The front is an extenſive range, forming the weſt ſide of Radcliffe-ſquare, with a ſquare tower in the centre decorated with architectural ornaments. The ſmall court is occupied by the library and chapel, and was erected in the ſeventeenth century, from plans, as ſome aſſert, by ſir Chriſtopher Wren, while a very young man at college. The architecture is of the mixed kind; arched windows and battlements are here oppoſed by Grecian pilaſters and capitals.

Corpus Chriſti College was founded and endowed by Richard Fox, biſhop of Wincheſter. This prelate had de-

ſigned and partly executed a collegiate eſtabliſhment for monks and ſecular ſcholars, to be ſubordinate to the priory of St. Swithin, in Wincheſter, but was induced to alter his plan, by the advice of Hugh Oldham, biſhop of Exeter, and to found a college for the ſtudy of divinity, philoſophy, and literature. He accordingly obtained a charter to that effect, dated March, 1516, and ſhortly after drew up a body of ſtatutes, declaring the ſociety to conſiſt of a preſident, twenty fellows, twenty ſcholars, two clerks and two choriſters. He likewiſe appointed two lectures for Greek and Latin, a meaſure which ſoon raiſed the reputation of the college to the higheſt pitch, as the founder conferred thoſe offices on men of eſtabliſhed fame and acknowledged erudition. The benefactors of this college are not ſo numerous as thoſe of ſome other colleges, but the donations were in general liberal, and the ample proviſion of the founder rendered additional contributions the leſs requiſite. Biſhop Oldham above-mentioned gave 6000 marks, beſides ſome eſtates in land, and Dr. Turner 6000*l.* The members of the college are the ſame as thoſe preſcribed by the charter, with the addition only of four exhibitioners and ſix gentlemen commoners. The biſhop of Wincheſter is viſitor.

Of the buildings of this college, the ſpacious quadrangle alone, with the chapel, hall, and library, was built by biſhop Fox. This court is entered by a gateway under a lofty ſquare tower in the centre of the principal front. On the eaſt ſide is the hall, and on the ſouth the library, which laſt is decorated with a ſtatue of the founder in his pontifical robes. The rooms to the eaſt of the quadrangle were firſt built in 1667, and re-erected in 1737, for the reſidence of the ſix gentlemen commoners. The fine building which looks into Chriſtchurch walks owed its conſtruction to Dr. Turner, and is appropriated for the reception of ſtudents. The library is enriched with an invaluable ſet of Aldine claſſics, and with numerous curious MSS. and rare works in a ſtate of excellent preſervation. The Aldine claſſics were collected by the founder.

Chriſtchurch College is indebted for its origin to the munificence of the celebrated cardinal Wolſey, who has been juſtly ſtyled the Mæcenas of his age. This prelate began the great work in queſtion in the year 1524, upon a ſcale far ſurpaſſing the deſign of any former or ſucceeding founder. By the original charter, which he procured from king Henry VIII., his projected eſtabliſhment was made to conſiſt of one hundred and ſixty perſons, who were to apply themſelves to the ſtudy of the ſciences at large, as well as to polite literature. For the ſupport of this ſociety he ſettled upon it a clear annual revenue of 2000*l.* and commenced the preſent ſtructure for the accommodation of its members, under the deſignation of "Cardinal College." Before he had completed his plans, however, he was hurled from the lofty pinnacle of power to which he had riſen, and plunged into irretrievable diſgrace: but before his death he warmly recommended his college to the foſtering regard of his monarch. Accordingly Henry, after the firſt effuſions of his reſentment had ſubſided, yielded to the entreaties of the ſociety in 1532, and became its patron. But in order to preclude Wolſey from all nominal participation in the merit of the undertaking, he granted the college a new charter of foundation, directed that its members ſhould conſiſt of a dean and twelve canons, and that it ſhould be called "King Henry VIIIth's College in Oxford." This arrangement, however, only continued for twelve or thirteen years, at the end of which period the ſociety yielded up their charter and poſſeſſions to the king, who converted the college into a cathedral church, by tranſlating the epiſcopal ſee hither from Oſeney. The inſtitution now became an appendage to the cathedral, and received the name of "The Cathedral Church of Chriſt in Oxford, of king Henry the VIIIth's foundation." At the ſame time the ſociety was declared to conſiſt of a biſhop, with his archdeacon, a dean, and eight canons, who had all the college eſtates made over to them on condition of their maintaining three profeſſors of divinity, Hebrew, and Greek, one hundred ſtudents in theology, arts, or philoſophy, eight chaplains, and a numerous choir. The king is viſitor of this college.

The benefactors to Chriſt-church are few, and all of them appeared at a period long ſubſequent to its foundation. Among the principal of them were the celebrated Dr. Buſby of Weſtminſter, who bequeathed a ſum of money for a catechetical lecture; biſhop Fell, who contributed ten exhibitions of 10*l. per annum* each; and Dr. Lee, phyſician to George II. who left 20,000*l.* for the purpoſe of erecting an anatomical theatre.

The buildings of this magnificent college occupy the area of the ancient priory of St. Frideſwide, and have undergone as many revolutions as the ſociety itſelf. They are chiefly arranged round four courts, two of which are very ſpacious. The great weſt quadrangle is particularly intereſting, as being the work of Wolſey, and indicates, that if that illuſtrious founder had ſurvived till he had been enabled to complete the deſign he appears to have formed, his college would have exceeded in magnificence every other in Europe. This quadrangle is entered by the gateway of the principal front, which extends 382 feet, and is adorned in the centre by a ſtately tower begun by Wolſey, but only completed in 1681, by ſir Chriſtopher Wren. All the buildings here are beautifully proportioned, and are faced with a fine terrace, as well as ſurmounted by a handſome ſtone balluſtrade. The hall and kitchen are on the ſouth, and on the eaſt and weſt ſides are ſplendid ranges of lodgings for the dean and canons. The hall occupies more than one-half of an entire range, and was begun and finiſhed under the direction of the founder. This room is 115 feet in length, 40 in breadth, and 50 in height. The roof is of oak, carved in an elaborate ſtyle. "The windows are interſected Gothic, and one in a receſs on the ſouthern ſide is among the fineſt ſpecimens of that mode of architectural diſpoſal." The ſide walls are of panelled wainſcot, and diſplay an extenſive collection of portraits, among which are an original half length of cardinal Wolſey, a whole length of king Henry VIII. another of queen Elizabeth, and a third of Dr. Buſby, with a pupil in attendance.

The ſecond great quadrangle of this college, termed Peckwater court, was erected at the commencement of the laſt century, and contains the library on its ſouthern ſide. This edifice is 141 feet long in front, and is adorned with maſſive pillars in the Corinthian ſtyle. Each of the other ſides is appropriated as lodgings for ſtudents. Their elevation is three ſtories, the lower of which is ruſtic, and "ſupports a range of architecture of the Ionic order," finiſhed by an entablature and balluſtrade of ſtone. In the library, which is rich in MSS. prints, and coins, is likewiſe a very noble collection of paintings, bequeathed to the college by brigadier-general Guiſe in 1765. Moſt of theſe paintings are by the old maſters, and muſt have been collected at an immenſe expence.

The two ſmaller courts are denominated Canterbury ſquare and Chaplain's court. Of theſe the firſt only deſerves to be noticed, being now the principal entrance into the college. It ſtands on the ſcite of Canterbury hall, which was founded in the fourteenth century by archbiſhop Iſlip, as a place for the ſtudy of the canon and civil law. The

deſign

deſign of this court was furniſhed by James Wyatt, eſq. architect, and the whole carried into execution under his direction. It was completed in 1783, chiefly through the munificence of Richard Robinſon, baron Rotheby, late lord primate of Ireland.

The cathedral of Chriſtchurch, to which the college is appended, will be noticed in the ſequel under the head of churches.

Trinity College was founded by ſir Thomas Pope, in the reign of Philip and Mary, from whom he obtained a royal licence and charter, dated the 8th and 28th March 1554. The ſociety was then made to conſiſt of a preſident, a prieſt, twelve fellows, and eight ſcholars, but the latter were ſoon increaſed to twelve. Theſe he placed in the tenements called Durham college, which he purchaſed and repaired for their accommodation. In 1556 he drew up a body of ſtatutes for their regulation, under the auſpices of the celebrated cardinal Pole, to whom it is ſuppoſed he was indebted for many uſeful hints. The ſame ſtatutes are ſtill in force, with ſome ſlight alterations made by the firſt preſident, with the conſent of the founder, after the re-eſtabliſhment of the Proteſtant worſhip, on the acceſſion of queen Elizabeth.

The endowment of this inſtitution by ſir Thomas was only limited by the extent of his means, which were happily ample. In May 1556 he gave the ſociety one hundred pounds; and before the cloſe of that year made over to them no fewer than thirty-five manors and thirteen advowſons, beſides impropriations and penſions. So liberal, indeed, was his donation, that with the exception of the contributors towards the new buildings few perſons have deemed it requiſite to become benefactors to this college, ſo that the ſociety remains nearly in the ſame ſtate as when originally founded, with the addition only of gentlemen commoners and commoners. The biſhop of Wincheſter is viſitor.

Architecturally conſidered, this college conſiſts of two courts. The firſt contains the chapel, the hall, the preſident's lodgings, the library, and ſome apartments for the fellows and ſcholars; and the latter is wholly occupied by lodgings for the reception of ſtudents. The chapel was built chiefly at the expence of Dr. Bathurſt, as is generally ſuppoſed after a deſign by dean Aldrich, corrected and improved by ſir Chriſtopher Wren. The interior is highly decorated. In a receſs at the upper end of this chapel is a monument in honour of ſir Thomas Pope, and of his third lady, with their whole length figures ſculptured in alabaſter.

St. John's College.—All the colleges hitherto noticed have owed their origin to the munificence of diſtinguiſhed ſtateſmen, or prelates; but we now come to one which was founded and endowed by an individual, whoſe fortune was gained by induſtrious exertions in the mercantile world. This was ſir Thomas White, a citizen and merchant of London, and one of the moſt liberal and benevolent characters of his age. The ſpot ſelected for the new foundation was the ſcite of St. Bernard's college, the buildings of which, indeed, ſtill form a ſmall portion of the preſent college. Here ſir Thomas fixed his ſociety in 1557, ſhortly after he had obtained a licence and charter for its inſtitution, and in the ſame year drew up a body of ſtatutes, declaring that it ſhould conſiſt of a preſident, fifty fellows and ſcholars, three chaplains, three clerks, and ſix choriſters; but the twelve laſt-mentioned members were ſoon diſcontinued, the funds being found inadequate to their proper ſupport. A ſuitable choir, however, has ſince been founded by ſir William Paddy, one of the numerous benefactors who have contributed to enrich the ſociety at different periods. Among theſe the chief were archbiſhops Laud and Juxon, and Dr. William Holmes and his lady. All the fellows of this college, except ſix of the founder's kindred, and two from Coventry, two from Briſtol, two from Reading, and one from Tunbridge ſchools, are elected from Merchant Tailor's ſchool in London, ſir Thomas having been a member of that reſpectable corporation. The biſhop of Wincheſter is viſitor.

The buildings of St. John's college, as they at preſent ſtand, have been erected at various periods. They are arranged chiefly in two quadrangles, one of which ſtill retains a part of the tenements which compoſed Durham college. In this diviſion are the hall and chapel, the preſident's lodgings and chambers for the fellows and ſcholars. The principal entrance is under a ſquare tower adorned with a ſtatue of St. Bernard placed in a richly canopied niche. On the eaſt ſide is a paſſage leading into the ſecond quadrangle, which contains the library, and was erected at the ſole expence of archbiſhop Laud, from a deſign by Inigo Jones. In the centre, both on the eaſt and weſt ſides, is a gateway of the Doric order, ſurmounted by a ſemicircular pediment of the Ionic and Corinthian, and having a ſtatue on either ſide between the columns. Theſe repreſent king Charles I. and his queen, and "were deſigned and caſt in braſs by Fanelli of Florence." The apartments, in the ſame range with the gateways, are built over cloiſters, ſupported by eight round arches, and adorned with buſts of the cardinal and Chriſtian virtues over each pillar. The library here is enriched with a valuable collection of books and MSS. and a variety of antiquarian curioſities.

Jeſus College owes its foundation to Hugh ap Rice or Price D.D. firſt prebendary of Rocheſter and treaſurer of St. David's. This benevolent character, obſerving that his countrymen, the Welſh, were ſcarcely ever noticed in collegiate endowments, reſolved to found a college peculiarly for their benefit, and with this view prevailed on queen Elizabeth to inſtitute the preſent eſtabliſhment by charter dated June 27, 1571. This deed preſcribed that the college ſhould be erected by the name of "Jeſus College, within the city and univerſity of Oxford, of queen Elizabeth's foundation," and declared the ſociety to conſiſt of a principal, eight fellows, and eight ſcholars. It further permitted Dr. Price to ſettle upon them an annual revenue of 160*l.*, to which he added a donation of 1500*l.* to aſſiſt in erecting the buildings, beſides a ſmall ſum which he bequeathed for the ſame purpoſe at his death. The queen, though nominally foundreſs, beſtowed little patronage and ſtill leſs property on her college, a circumſtance not a little remarkable, as we believe this to have been the firſt college in Oxford which could boaſt of deriving its origin from a Proteſtant benefactor. Hence, when Dr. Price died the funds of the ſociety were ſo much exhauſted as to ſtop for a time the progreſs of the buildings. But private munificence ſoon after ſupplied the want of regal bounty. The buildings were gradually completed, and many extenſive benefactions quickly added ſtability to the hitherto limited finances of the inſtitution. Sir Eubule Thelwall, beſides liberal donations, procured for the ſociety a new charter, dated June 1, 1622. Dr. Williams founded a logic lecture, and ſir Thomas Canon a catechetical lecture. Among the other more extenſive contributors were Henry Weſtphaling, biſhop of Hereford; Henry Rowlands, biſhop of Bangor; king Charles I.; Francis Manſell, D.D.; ſir Leoline Jenkins; and Edward Merrick M.A., treaſurer of St. David's; ſome of whom added new fellowſhips and ſcholarſhips. Theſe additional revenues rendered new charters neceſſary at different periods. The laſt was granted by George II. January 10, 1729, and under it the ſociety now conſiſts of a principal, nineteen fellows, and eighteen ſcholars,

lars, beſides a number of exhibitioners, &c. The earl of Pembroke is viſitor.

The buildings of Jeſus college form two quadrangles, the firſt of which meaſures 90 feet by 70, and the ſecond 100 feet by 90. The former, entered from the ſtreet, contains the chapel on the north and the hall on the eaſt ſides. The other ſides are occupied by apartments of three ſtories high. The front, in the ſtreet, was rebuilt in 1756, and is a heavy erection, deſtitute alike of intereſt and beauty. The ſecond, or inner quadrangle, was begun in 1640, under the management of Dr. Manſell, then principal; but the diſturbances ariſing from the rebellion prevented its completion till the year 1676, when it was finiſhed by ſir Leoline Jenkins, at his own expence. The library, on the weſt ſide of this quadrangle, contains a good collection of books and ſome curioſities, among which are an immenſe ſilver bowl, weighing 278 ounces, and capable of holding above ten gallons; a metal watch given by Charles I.; and a huge ſtirrup, ſaid to have been preſſed by the foot of queen Elizabeth. The chapel, built in 1621, is divided into three parts by two ſcreens. The roof is finiſhed in compartments, and is very richly decorated.

Wadham College was founded by Nicholas Wadham, eſq. and his wife Dorothy, daughter of ſir William Petre, an eminent benefactor to ſeveral colleges in this univerſity. The execution of the undertaking, however, wholly devolved on the latter, as Mr. Wadham himſelf died before the plan he had propoſed could be carried into effect. Her firſt ſtep was to purchaſe the ſcite of the ancient priory of Auſtin friars, once a place of great diſtinction in the univerſity, which ſhe accompliſhed in 1610, and on the 31ſt of July, in the ſame year, laid the firſt ſtone of the preſent college. A royal licence was obtained in 1611, and in 1612 the ſtatutes promulgated by the foundreſs received the ſanction of an act of parliament. By theſe ſtatutes, which ſtill continue in force, except as to the ſubject of marriage, the college was made to conſiſt of a warden, fifteen fellows, fifteen ſcholars, two chaplains, and two clerks. To theſe, however, ſeveral exhibitions have been added by ſucceſſive benefactors, among whom the late Dr. John Wills, who died in 1806, deſervedly holds the firſt rank. This gentleman bequeathed 400*l.* a-year to the wardenſhip; 1000*l.* to improve the warden's lodgings; two exhibitions of 100*l.* *per annum* each to two fellows, ſtudents in law or medicine; two exhibitions of 20*l.* to ſcholars in the ſame faculties; 20*l.* a-year for a divinity lecturer; an annual exhibition of 75*l.* and another of 100*l.* to two ſuperannuated fellows; 11*l.* 10*s.* to a preacher; and 6*l.* a-year for the purchaſe of books to be given as a premium to the beſt reader in the chapel. He further nominated the ſociety his reſiduary legatee.

The buildings are entirely compriſed in one very ſpacious quadrangle, about one hundred and thirty feet ſquare; the whole of which, with the exception of a building of three ſtories on the ſouth of the front, were erected by the foundreſs, at the expence of 10,816*l.* 7*s.* 8*d.* This college is entered by a gateway, under a central tower, and has on its eaſtern ſide the hall and chapel, and on the other three, the warden's lodgings, and apartments for the fellows, ſcholars, and ſtudents. In the middle of the eaſtern ſide is a portico in four compartments, adorned with ſtatues in canopied niches of the founder and foundreſs, and of king James I., whoſe arms, ſculptured in ſtone, are placed in the higheſt compartment. The biſhop of Bath and Wells is viſitor.

Pembroke College owes its foundation to the joint munificence of Thomas Teſdale and Richard Wightwick; for though in the charter, which is dated 1624, king James is denominated founder, and the earl of Pembroke, the chancellor of the univerſity, godfather, yet they in fact contributed little or nothing towards its eſtabliſhment, further than what their patronage may be ſuppoſed to have accompliſhed. According to the ſtatutes drawn up, agreeably to the charter, the ſociety was made to conſiſt of a maſter, ten fellows, and the ſame number of ſcholars; but the fellows have ſince been increaſed to fourteen, and the ſcholars and exhibitioners to twenty-one, by the liberality of different benefactors, among whom the moſt eminent were lord Oſſulſton, grandſon to the founder Teſdale, and George Morley, biſhop of Wincheſter. The chancellor of the univerſity is viſitor.

Pembroke college now forms two ſmall courts, which are built on the ancient ſcite of Broadgate's hall, ſome portion of which is ſtill ſtanding, and conſtitutes the hall of the preſent college. The principal court is uniform in its architecture, and poſſeſſes the merit of ſimplicity. It was chiefly erected at different periods during the ſeventeenth century, partly with the money of the founders, and partly by the aid of ſubſequent contributions. The front, which was only completed in 1694, is an unadorned elevation, with a low tower over the entrance in the centre. The chapel is a ſmall, but elegant edifice of the Ionic order, and is richly ornamented within.

Worceſter College was founded in 1714, under the will of ſir Thomas Cookes of Bentley Pauncefort, in Worceſterſhire, who died in 1702, and bequeathed 10,000*l.* to be applied either in eſtabliſhing a new college, or in the endowment of additional fellowſhips and ſcholarſhips in ſome previous eſtabliſhment. The truſtees at firſt heſitating which of the above plans to adopt, the money accumulated to 15,000*l.* before they came to the reſolution of founding the preſent inſtitution. This, however, they at length determined on, and a charter of incorporation was obtained in 1714 for a college, to be called "The Provoſt, Fellows, and Scholars of Worceſter College, in the Univerſity of Oxford." A body of ſtatutes were framed about the ſame time, and the ſociety ſettled in the ancient tenements of Gloceſter hall, ſome part of which ſtill remains. Several liberal benefactors ſoon after added conſiderable donations. Of theſe, the principal were Dr. James Fynney, George Clarke, D. C. L., and Mrs. Sarah Eaton, the laſt of whom endowed ſeven fellowſhips and five ſcholarſhips for the ſons of clergymen only. Hence the ſociety now conſiſts of a provoſt, twenty-one fellows, and fifteen ſcholars. The viſitors are the biſhop of Oxford and the vice-chancellor of the univerſity. A preference is given in the choice of ſtudents, on the original foundation, to perſons educated in the founder's ſchools of Bromſgrove and Feckenham, and to his own kindred.

The ſituation of Worceſter college is on the weſtern ſide of the city, on an eminence near the bank of the river Iſis. The buildings form a court, the ſouth ſide of which is ſtill occupied by a range of old apartments, but its other diviſions are all of modern erection, and compriſe a chapel, a hall, a library, and lodgings for the accommodation of members and ſtudents. The architecture of theſe portions is grand and impoſing, though ſimple and devoid of ornament. The library, however, is ſupported by a ſpacious cloiſter in the front towards the court, and is particularly remarkable for a valuable collection of architectural books and manuſcripts.

Hertford College, the laſt we have to notice, was the ancient Hart hall, which was founded by William Stapledon, biſhop of Exeter, and continued attached to Exeter college till the year 1740, when it was elevated to the rank of an independent college by Dr. Newton, who beſtowed upon it his whole property. This, however, has proved inſufficient for its intended purpoſes, and as few benefactors have appeared

peared in aid, the inſtitution is now much declined. Since 1805 it has had no principal, and at preſent there is only one fellow, though by the ſtatutes the ſociety was made to conſiſt of a principal, four ſenior fellows, and eight junior fellows or aſſiſtants. The chancellor of the univerſity is viſitor.

According to the deſign of Dr. Newton, the buildings of this college were to have formed one ſpacious quadrangle, containing a chapel, hall, and library, lodgings for the principal, and apartments for the ſociety. Of this plan only a part has hitherto been carried into execution, and that by the founder himſelf, no additions having been made ſince his death. The portions of Hart-hall ſtill remaining are, the refectory, built in the reign of queen Elizabeth, the old principal's lodgings, with the kitchen and chambers over them, and the gatehouſe and library.

Before particularizing the *halls*, it may be proper to obſerve, that previous to the foundation of colleges all the univerſity ſtudents lodged in tenements rented by citizens of Oxford, and that when a tenement was once ſo appropriated, the proprietor could never again recover it for other purpoſes, nor ſell or demiſe it, without binding the purchaſer to leave it open to the uſe of the univerſity, if required. When an advance of rent was demanded, the reaſonableneſs of the demand was determined by the arbitration of two maſters on the one part, and two citizens on the other, who were ſworn to do juſtice between the parties. Such places of education are of conſiderable antiquity, and were, probably, as we have already hinted, at firſt appended to monaſtic inſtitutions. In the time of Edward I. they are ſaid to have exceeded three hundred in number, but after the endowment of colleges began, they rapidly ſunk into neglect, and now only five remain, one of which is deſtitute of ſtudents. Each hall is governed by a principal, under the guidance of ſtatutes originally drawn up by the principal of the univerſity, and alterable at his pleaſure. This officer is officially viſitor of all the halls, and has the power of nominating the whole of the principals, except the principal of St. Edmund's hall, who is elected by the provoſt and fellows of Queen's college. The ſtudents in theſe halls have equal univerſity privileges with thoſe belonging to the colleges, and are ſubject to the ſame regulations with reſpect to diſcipline, courſe of ſtudies, tuition, length of reſidence, examinations, dreſs, &c.

St. Alban's Hall, the moſt ancient of thoſe now remaining, is ſituated on the eaſt ſide of Merton college. This hall derived its name from Robert de Sancto Albano, a burgeſs of Oxford, in the reign of king John. In the time of Henry VI. it was united to Nunne hall, which ſtood weſt from it, but its principals were appointed by Merton college. Henry VIII. granted both halls conjoined, in the name of Alban hall, to his phyſician, from whom it paſſed to different proprietors, and is now the property of the warden and fellows of Merton college. The buildings of this hall form a quadrangle, plain in its architecture, but commodious in reſpect to internal arrangements.

Edmund Hall is traditionally ſo called from St. Edmund, archbiſhop of Canterbury, in the reign of Henry III. At the diſſolution it belonged to Oſeney priory, and ſoon after that event came into the poſſeſſion of Queen's college, and was renewed as a place of ſtudy under the auſpices of that inſtitution, to which it ſtill continues attached. Several extenſive additions to the old buildings of this hall have been made during the two laſt centuries, chiefly by the liberality of its own members, and thoſe of Queen's college. The library, begun in 1680, has been enriched by ſeveral valuable collections of books and MSS. This portion of the buildings, as well as the chapel, was erected by Stephen Penton, B.D. principal, and chiefly at his own expence.

St. Mary's Hall was anciently conveyed to the rectors of St. Mary's church for a parſonage houſe, and remained in their poſſeſſion till the year 1325, when Edward II. gave it, with the advowſon of the church, to the ſociety of Oriel college, who converted it into an academical hall in 1333, under its preſent appellation. The buildings are arranged in the form of a quadrangle, containing lodgings for the principal on the north, a hall and chapel on the ſouth, and apartments for the ſtudents on the weſt and eaſt, all of which have either been rebuilt, or much improved within the laſt century.

New Inn Hall is now entirely gone to decay, the only part of its buildings now remaining being a houſe for the principal, who is only nominally ſuch, there having been no ſtudents at this hall for many years. It was, at one time, however, very famous for ſtudents of the civil and canon law, and produced many eminent characters in that faculty. In 1642 it was occupied as a mint by king Charles I., who here melted down the plate preſented to him by the univerſity.

St. Mary Magdalen Hall was founded as a grammar ſchool in 1480, by William Waynflete, founder of Magdalen college, to which it immediately adjoins. It was firſt called Grammar hall, but received the name of Magdalen hall upon being enlarged, and placed upon the ſame footing with reſpect to academical privileges as the other halls. This foundation appears to have been generally in a very flouriſhing condition, and at one time is ſaid to have had nearly three hundred members, but it is difficult to conceive how ſo many perſons could be accommodated within its walls. Dr. William Lucy, and ſome other benefactors, have eſtabliſhed a number of exhibitions in this hall for the benefit and encouragement of the ſtudents. A part of the buildings has likewiſe been erected by the munificence of private individuals, among whom Dr. John Wilkinſon, principal from 1605 to 1643, and his ſucceſſor Henry Wilkinſon, are deſervedly the moſt noted. The latter built the library, and procured for it a good collection of books, which have been ſince increaſed by various contributions.

Public Inſtitutions connected with the Univerſity.—Beſides the colleges and halls there are ſeveral public buildings and eſtabliſhments, which either owe their origin to the univerſity, or are placed under the management of its officers. The principal of theſe are the ſchools; the Bodleian library; the theatre; the Clarendon printing-houſe; the Radcliffe library; the Aſhmolean muſeum; the obſervatory; the phyſic garden; and St. Mary's, or the Univerſity church, which laſt will be noticed under the head of churches.

The firſt *Public Schools* were erected about the commencement of the fifteenth century, by Thomas Hokenorton, abbot of Oſeney, and conſiſted of ten apartments, allotted to different branches of education. To theſe were added the divinity ſchool in the year 1427, the erection of which was chiefly effected by the liberality of Humphry, duke of Glouceſter, uſually ſtyled the Good. This laſt is ſtill ſtanding, and is a curious ſpecimen of architecture. All the others, however, were demoliſhed in the beginning of the ſeventeenth century, when the preſent ſchools were erected, which, with part of the Bodleian library, form a quadrangle of about one hundred and ſeventy feet in length. Over the gateway is a lofty tower, fantaſtically arranged in compartments, exhibiting an imitation of the five orders of claſſic architecture (See Britton's Architectural Antiquities, vol. iii.) The whole quadrangle is now three ſtories high, two of which are appropriated as ſchools, while the third and higheſt is occupied

occupied as a picture gallery, and contains a numerous and ſplendid collection of the portraits of founders, benefactors, and other eminent perſons connected with the univerſity. The ſchools are governed by three maſters, who cannot hold their office more than two years in ſucceſſion. The public profeſſors read lectures here in the different ſciences, and here alſo the ſcholars of the univerſity are obliged, by ſtatute, to perform the exerciſes required of them, before they can obtain their degrees. In the moral philoſophy lecture room is preſerved a collection of ſtatues, marbles, and buſts, the gift of the counteſs dowager of Pomfret; and in an apartment on the north ſide of the ſchools, are ranged the Arundelian marbles, together with numerous other monuments of Grecian antiquity, collected by Selden, Wheeler, and others, and preſented or bequeathed to the univerſity.

The *Bodleian* or *Public Library* was founded by ſir Thomas Bodley at the cloſe of the ſixteenth century, on the remains of that which was eſtabliſhed by the duke of Glouceſter above-mentioned, but had been diveſted of all its valuable books and illuminated MSS. by the commiſſioners of Edward VI. This library occupies three extenſive rooms, diſpoſed in the form of the letter H, and probably contains the moſt valuable collection of books and MSS. in Europe, as the donations in aid of ſir Thomas's contribution have been ſplendid and liberal beyond precedent. Among thoſe who had added whole libraries to the original collection, are the earl of Pembroke, Mr. Selden, archbiſhop Laud, ſir Thomas Roe, ſir Kenelm Digby, general Fairfax, Dr. Marſhall, Dr. Barlow, Dr. Rawlinſon, Mr. St. Amand, Dr. Tanner, Mr. Willis, T. Hearne, Mr. Godwin and Mr. Gough. The laſt contributed all his topographical collections, books, prints, copper plates, and drawings.

The ſtatutes by which this library is governed, were drawn up by ſir Thomas Bodley, who, beſides his books, left an eſtate to the univerſity for the proviſion of ſuitable ſalaries to its officers, and for the repair of the buildings. Theſe ſtatutes are preſerved in the founder's own hand writing, in the archives of the library, and contain, among other clauſes, one appointing the vice-chancellor, proctors, and the regius profeſſors of divinity, law, medicine, Hebrew and Greek, viſitors or curators. The Rev. Bulkley Bandinel, M.A. is librarian.

The *Theatre*, or *Selden Theatre*, in which are held all the acts called the Encœnia, and Comitia, alſo lord Crewe's annual commemoration of benefactors, was built at the ſole charge of archbiſhop Selden, who, beſides, gave the ſum of 2000*l.* as a fund for repairs. The architect was ſir Chriſtopher Wren, who, in the plan and conſtruction of this edifice, gave a happy preſage of thoſe talents which he afterwards diſplayed in the metropolis. By an ingenious diſpoſition of its parts he has contrived to render it capable of holding nearly four thouſand perſons, though its dimenſions ſeem altogether inadequate for that purpoſe. The roof is eighty feet by ſeventy, and reſts entirely on the ſide walls, without any central ſupport. The exterior elevation on the ſide oppoſite to the divinity ſchool is adorned with columns of the Corinthian order, and ſtatues, in niches, of the founder, and the duke of Ormond.

The *Clarendon Printing-houſe* was erected in 1711, with the profits ariſing from the ſale of lord Clarendon's Hiſtory of the Rebellion, the copyright of which was preſented to the univerſity by his lordſhip's ſon. It is a maſſive ſtructure, two ſtories high, adorned in front with a portico of the Doric order, and has a ſtatue of the noble author over the ſouthern entrance. The buſineſs of this houſe is ſuperintended by perſons termed delegates of the preſs, who are appointed by the vice-chancellor and proctors.

The *Radcliffe Library*, which is certainly one of the moſt impoſing architectural ornaments of the univerſity, was founded by Dr. Radcliffe, an eminent phyſician in the reigns of king William and queen Anne, he having bequeathed 40,000*l.* for its erection, 150*l. per annum* for a librarian, and 100*l. per annum* for the purchaſe of books. The building itſelf was deſigned and executed by Gibbs, between the years 1737 and 1749; and ſome of the firſt artiſts of the age were employed on its interior embelliſhments. Exteriorly, a ruſtic baſement, in the form of a double octagon, ſupports a cylindrical ſuperſtructure, adorned with three-quarter Corinthian columns, ranged in couplets, between which are windows and niches alternately. A baluſtrade, finiſhed with vaſes on the piers perpendicular to the columns, ſurmounts the entablature, and the whole elevation is terminated by a fine cupola ſixty feet high, which renders this building a ſtriking feature in every diſtant view of the city. The contributions to this library are few, compared to thoſe to the Bodleian, which ſeems almoſt to have wholly engroſſed the munificence of the learned.

The *Aſhmolean Muſeum* owes its foundation to Elias Aſhmole, author of the Hiſtory of the Garter, who offered to beſtow on the univerſity all the extenſive collections in natural hiſtory which had been bequeathed to him by the two Tradeſcants, the celebrated naturaliſts and phyſic gardeners at South Lambeth, (ſee MUSEUM,) and to add to theſe his own coins, medals, MSS. and books, provided the univerſity would defray the expence of erecting a proper building for their reception. This offer was accordingly accepted, and the preſent edifice raiſed, under the direction of ſir Chriſtopher Wren. The contributors to this muſeum have been numerous. The chief of them were Dr. Plot, Mr. Llwyd, Mr. Borlaſe, and Mr. Reinhold Foſter. The contribution of this laſt conſiſts chiefly of curious articles from the South Sea iſlands. This building likewiſe contains the books of Dr. Liſter, and the MSS. of Dugdale, Aubrey, and Wood.

The *Aſtronomical Obſervatory* was built at the expence of 30,000*l.* defrayed by the truſtees of Dr. Radcliffe. It is ſituated at the extreme end of the north ſuburb, on a very appropriate ſcite with attached grounds, which were preſented to the univerſity by the duke of Marlborough. The central elevation of this edifice is upwards of 100 feet, and its third ſtory conſiſts of an octangular tower, with ſculptural repreſentations of the eight winds on the entablature, and a ponderous earth-coloured globe at the top. The whole ſtructure compriſes a dwelling-houſe for the obſerver, apartments for obſervation, for an aſſiſtant obſerver, and for lectures, and is ſupplied with a valuable ſet of aſtronomical inſtruments, beſides a library. See OBSERVATORY.

The *Phyſic Garden*, compriſing about five acres of ground, is ſituated oppoſite to Magdalen college, on the ſouth, and is encompaſſed by a lofty wall, with a handſome gateway, which was deſigned by the celebrated Inigo Jones. Over the arch of this gateway is a buſt of the founder, Henry Danvers, earl of Danby, and on the right and left are ſtatues of Charles I. and II. The garden is arranged in four quarters, and is provided with ſuitable green-houſes, and a hot-houſe for the reception of the more tender and exotic plants. The chief contributor to this garden was Dr. Sherard, who in 1728 left three thouſand pounds for the endowment of a profeſſorſhip of botany; and in 1793 a Regius profeſſor in that ſcience was likewiſe appointed by his preſent majeſty.

Government and Civil Hiſtory of Oxford.—The corporation of this city, eſtabliſhed both by charter and by preſcription, is governed by a mayor, a high ſteward, recorder, four aldermen, eight aſſiſtants, two bailiffs, a town-clerk,

clerk, two chamberlains, and twenty-four common-counſellors. By grant from Henry I. the mayor, for the time being, acts in the buttery at the coronation feaſts of the kings and queens of England; and hence, as well as from other cauſes, many of them have received the honour of knighthood. Oxford ſends two members to the national ſenate, and has done ſo, according to Willis, in his Notitia Parliamentaria, ſince the firſt inſtitution of a parliament in this iſland. The electors are the corporation and freemen, and the returning officers, the mayor and bailiffs.

Oxford is divided into four wards, under the immediate juriſdiction of the four aldermen; and theſe again, with the ſuburbs, are ſubdivided into fourteen pariſhes; St. Mary's, All-Saints, Carfax, or St. Martin's, St. Clements, St. Ebbs, St. Giles's, the Holy Croſs in Holywell, St. John's, St. Mary Magdalen's, St. Michael's, St. Peter's in the Eaſt, St. Peter's in the Bailey, St. Aldgate's or St. Old's, and St. Thomas's. The whole of theſe contain, according to the parliamentary returns of 1811, 2064 houſes, and 12,931 inhabitants, of whom 1015 perſons belonged to the colleges.

Public Buildings belonging to the City.—Beſides the colleges and the public ſtructures already mentioned as peculiarly connected with the univerſity, there are ſeveral others erected for religious and municipal purpoſes, which cannot properly be paſſed over unnoticed. Of the firſt deſcription are the cathedral, the pariſh churches, and the chapels of diſſenters; and under the latter we ſhall include the town and county-hall, the Radcliffe infirmary, the Houſe of Induſtry, the town and county gaol, the city Bridewell, the ſchools and alms-houſes, and the range of buildings for the market.

The *Cathedral Church* is ſituated to the eaſt of the grand quadrangle of Chriſtchurch college. It was originally the church of St. Frideſwide's monaſtery, on the ſcite of which the college is erected. This edifice is referred by King, in his Munimenta Antiqua, to the era of the Saxons; but Dugdale, Tanner, and Willis, date its foundation in the time of Henry I.; and as their opinions are generally more rational and probable than thoſe entertained by Mr. King, we are fully diſpoſed to coincide with them on this point. In its architecture this church preſents the ſtyles and examples of different ages, from the time of the original building, up to the commencement of the 16th century. The church is built in the ſhape of a croſs, and meaſures one hundred and fifty-four feet in length. In the centre riſes a tower, with a ſpire to the height of one hundred and forty-four feet. Some of the windows contain fine ſpecimens of painted glaſs, and in the north aiſle is a monument attributed to St. Frideſwide.

St. Mary's Church, or, as it is ſometimes called, the Univerſity Church, is a beautiful ſtructure, in the pointed ſtyle of the reign of Henry VII. The ſouth porch, with twiſted columns, is however a deformed and taſteleſs appendage. The church is ſituated on the north ſide of High-ſtreet, and conſiſts of a ſpacious chancel, and three aiſles, with a ſquare tower and ſpire, one hundred and eighty feet high. The tower is ſupported by two graduated buttreſſes at each angle, and is finely ornamented with ſtatues in niches, pinnacles, &c. In this church the public ſermons of the univerſity are preached on Sundays and holidays; and it is conſequently fitted up in a manner proper for the reception of the ſeveral members of that diſtinguiſhed corporation. The pulpit ſtands in the middle aiſle, and at its weſtern end is the chancellor's throne, which is elevated ſeveral ſteps above the other ſeats. Cloſe to the throne are the ſeats of the proctors, and next to them, on either ſide, ſit the doctors and heads of houſes.

The church of *All-Saints* is ſituated in the ſame ſtreet with St. Mary's, but is a ſtructure of a very different kind, being of comparatively modern erection, and in the ſtyle of ſacred architecture, which ſir Chriſtopher Wren contributed to render popular. This edifice compriſes a nave, a chancel, and two aiſles, and its roof is ſupported entirely upon the ſide walls, there being no pillars within the church, though pilaſters of the Corinthian order are frequent. The tower is ſurmounted by a turret, encircled by Corinthian pillars, whence riſes a ſpire. Between the lower range of windows are pilaſters of the ſame character, diſpoſed in couplets. The architect of All-Saints was Dr. Aldrich, dean of Chriſtchurch, who alſo deſigned the buildings of Peckwater-ſquare.

St. Peter's in the Eaſt is an intereſting edifice, of a very ancient date. It is commonly ſaid to be the earlieſt ſtone church erected in this part of England. The preciſe date of its foundation, however, is uncertain, as the claims of St. Grymbald to be the founder, are at leaſt as doubtful as the ſtory of his profeſſorſhip, under the patronage of king Alfred. This church was formerly the univerſity church, and the vice-chancellor and heads of houſes ſtill attend divine ſervice here in the afternoon of the Sundays during Lent. It has a nave, chancel, and two ſide aiſles, with a tower at the weſt end. The chancel is a ſingular and curious ſpecimen of architectural deſign; particularly in the ribs beneath the ceiling, and in two windows. Beneath the chancel is a crypt, ſupported by ſix circular pillars with ſquare baſes and capitals. Some of the latter are charged with very rude, but ſingular ſculpture. See Architectural Antiquities, vol. iv.

St. John's Church, which is likewiſe the chapel to Merton college, is a rich ſpecimen of the architecture of the 15th century, and in higher preſervation than uſually happens with the buildings of that age. Its members are a choir, a croſs aiſle, an anti-chapel, and a ſquare tower, which riſes from the centre of the croſs aiſle, and is elegantly adorned with panelling and pinnacles. The windows, both of the choir and croſs aiſle, are filled with painted glaſs: ſo is likewiſe the great eaſt window, the maſonry of which is exquiſitely delicate. Near the altar of this church are the monuments of the diſtinguiſhed benefactors to the univerſity, ſir Thomas Bodley and ſir Henry Savile; and cloſe to the door is a ſmall mural tablet, commemorative of the celebrated Oxford hiſtorian, Anthony a' Wood.

Carfax, or *St. Martin's Church*, is compoſed of a nave, two narrow aiſles, and a chancel, with a tower at the weſt end, which was reduced to its preſent height in the time of Edward III., on a complaint by the ſcholars that the townſmen frequently took poſſeſſion of it "in time of combat," and annoyed them therefrom with ſtones and arrows, as from a caſtle.

St. Clement's Church is a ſmall building of one aiſle and a chancel, and a low tower at the weſt end. *St. Ebbs*, ſo called from Ebba, daughter of Ethelfrid, king of Northumbria, is likewiſe of ſmall dimenſions, containing a nave, north aiſle, and chancel. *St. Giles's* was erected in the 12th century, as ſome ſay, on the ſcite of an ancient Britiſh temple. This ſtructure conſiſts of a nave, chancel, and a north and ſouth aiſles, and has an embattled tower at the weſt end. *Holywell Church* is a ſmall building, ſuppoſed to have been erected by Robert de Oigli, the founder of the caſtle. *St. Michael's Church*, originally belonging to the canons of St. Frideſwide, is now a curacy incorporated into one collegiate church, with the college of Lincoln. The tower of this edifice is of great antiquity, but its other parts are of late erection. So likewiſe is the church of *St. Peter's in the Bailey*, which is a ſtone building, finiſhed in 1740. *St. Aldgate's*, on the other hand, is very ancient, having been uſed as a cloiſter to receive perſons training for the priory of St. Frideſwide

and Abingdon-abbey. It is an irregular pile, erected at different periods. *St. Thomas's* is alſo of ancient date, having been founded in 1141 by the canons of Oſeney, and dedicated firſt to St. Nicholas and afterwards to St. Thomas à Becket. This building conſiſts only of one aiſle and a chancel, with an embattled tower at the weſt end.

As diſſenters from the eſtabliſhed church are comparatively few in Oxford, meeting-houſes are neither frequent nor ſpacious in extent. Indeed, almoſt the only regular ſectarian chapels here are thoſe belonging to the Roman Catholics, the Quakers, the Methodiſts, and the Baptiſts.

Among what have been termed the municipal public buildings in Oxford, the *Town and County Hall* may properly claim the precedence as the ſeat of the courts of juſtice, and the focus of the municipal authority. It is a ſpacious edifice of ſtone, having a pediment over the centre of the front, which exhibits a range of ruſtic work in its lower diviſion. The expence of erecting it was chiefly defrayed by Thomas Rowney, eſq. late high ſteward of the city.

The *Radcliffe Infirmary* is one of the public edifices conferred on Oxford by the munificence of Dr. Radcliffe: it having been built by his truſtees with part of the funds remaining in their hands after the completion of the Radcliffe library. It is a ſtone building, well adapted for the reception of patients, and has extenſive grounds attached, the donation of T. Rowney, eſq. above mentioned. The charity is ſupported by voluntary ſubſcriptions.

The *Houſe of Induſtry* ſtands near the infirmary. It was built for the reception of the poor of eleven pariſhes, and is conſequently a ſtructure of conſiderable extent, but poſſeſſes no architectural features worthy of remark. The other principal charitable inſtitutions in Oxford are, Boulter's and Stone's alms-houſes, and four charity-ſchools, one of which, for fifty-four boys, is ſupported by the univerſity.

The *Town and County Gaol* is a large edifice of ſtone, with ſeparate lodgings, and yards of exerciſe for the debtors and felons. It occupies a part of the ſcite of the old caſtle, built by Robert de Oigli, and diſplays much more lightneſs and architectural taſte than is uſual in ſtructures of a ſimilar deſcription. It was deſigned and erected by D. Harris, eſq. architect.

The *City Bridewell* is a modern building, ſubſtantial in its conſtruction, and well arranged for the purpoſes to which it is appropriated. Before the erection of this edifice, in 1789, offenders, within the juriſdiction of the mayor, were placed in a priſon over the north-gate, called Bocardo, where Cranmer, Ridley, and Latimer were confined, and whence they were led to the ſtake. In a ſmall room, which forms the entrance to the Bridewell, is ſtill preſerved the door which is ſaid to have led to the cell of theſe illuſtrious martyrs.

The *General Market-houſe* is a commodious range of building, erected under the authority of an act of parliament, and certainly conſtituting one of the greateſt improvements effected during the laſt century. It is ſeparated into three diviſions, one appropriated to butchers, a ſecond to the venders of poultry, bacon, &c., and a third to the ſale of vegetables and fruits. Round the whole are ranges of ſhops under an arcade.

Monaſtic Antiquities of Oxford.—This city, as has been already hinted, contained no fewer than nineteen religious houſes prior to the reformation, ſome of which were converted into collegiate eſtabliſhments. The names of theſe monaſtic inſtitutions were as follows: 1. St. Frideſwide's priory; 2. St. George's college; 3. Oſeney abbey; 4. Rowley abbey; 5. St. Bernard's college; 6. Canterbury college; 7. Durham college; 8. Glouceſter-hall; 9. London college; 10. St. Mary's college; 11. St. Bartholomew's hoſpital; 12. St. John's hoſpital; 13. Auſtin Friars; 14. Black Friars; 15. Grey Friars; 16. White Friars; 17. Crouched Friars; 18. Friars de Sacco; and 19. Trinity-houſe.

St. Frideſwide's Priory is ſaid to have been originally founded for nuns of noble birth, by Didanus, an earl of Oxford, about the year 727, and to have derived its name from Frideſwide, his daughter, whom he appointed the firſt prioreſs. In 1111 it was made the ſeat of a ſociety of regular Auguſtine canons, and continued ſuch till its ſuppreſſion, when the ſcite and buildings were granted to cardinal Wolſey for his college of Chriſtchurch.

St. George's College ſtood within the caſtle. It was founded and endowed in 1074, by Robert de Oigli and Roger Iveri, for ſecular canons, who were diſperſed in 1149.

Oſeney Abbey was originally a priory for Auſtin canons, founded by Robert de Oigli, nephew to the founder of the caſtle, but was ſhortly after conſtituted an abbey. The abbey church was for a few years the cathedral church of the ſee of Oxford, at its firſt eſtabliſhment. This religious houſe was ſituated on one of the ſmall iſlets formed by the Iſis, at a ſhort diſtance from the ſcite of the caſtle, where its ruins may ſtill be traced.

Rowley or *Ruley Abbey* was founded by Edmund, earl of Cornwall, and filled with monks of the Ciſtercian order, about the year 1280. Some fragments of the buildings of this monaſtery ſtill remain in the weſtern ſuburbs.

St. Bernard's College was founded in 1436, by Henry Chichele, archbiſhop of Canterbury, for ſtudent monks of the Ciſtercian order. Its ſcite is now occupied by St. John's college, having been purchaſed by ſir Thomas White from the dean and canons of Chriſtchurch, to whom it had been granted at the diſſolution.

Canterbury College, founded by Simon de Iſlip, archbiſhop of Canterbury, for ſtudents in religion and civil law, is now included in Chriſtchurch college, having been granted to the dean and canons of that cathedral, ſhortly after the general ſuppreſſion.

Durham College ſtood on the ſcite now occupied by Trinity college It was founded and endowed in 1290, by the prior and monks of the cathedral convent of Durham, for young ſtudents of their own order. At the diſſolution, it was granted to the dean and chapter of that church, by whom it was transferred to ſir Thomas Pope.

Glouceſter Hall or *College* owed its origin to ſir John Giffard, lord of Brimesfield, A.D. 1283. After the ſuppreſſion, it became the palace of the biſhops of Oxford; but was ſoon reſumed by the crown, and ſubſequently fell into the poſſeſſion of ſir Thomas White. The buildings of this hall at preſent conſtitute a part of Worceſter college.

London College was originally Burnell's Inn, but changed its deſignation about the year 1421; from which time it was inhabited ſolely by black monks and ſecular ſtudents in the civil law, till its diſſolution.

St. Mary's College was founded in 1435, by Thomas Holden and his wife, for ſtudent canons of the Auguſtine order. The ſcite of it was granted by Henry VIII. to William Rameſden and Richard Vaſavor.

St. Bartholomew's Hoſpital ſtands about half a mile eaſtward from the city. It is of great antiquity, and generally ſuppoſed to have been founded by Henry I. King Edward III. gave it, A.D. 1328. to Oriel college, upon condition of that ſociety maintaining therein a chaplain and eight poor brethren.

St. John's Hoſpital, which occupied the ſcite of the preſent college of St. Mary Magdalene, was in exiſtence as early as the reign of king John; but the preciſe date of the original foundation is unknown. It appears, however, to have

have been new founded, or at leaſt new built, A.D. 1233, by king Henry II., who laid the firſt ſtone himſelf. In 1456 it was conveyed to William Waynflete, biſhop of Wincheſter, who erected on its ſcite his magnificent college.

The *Auſtin Friars* founded a priory here in 1268, on a piece of ground in the pariſh of Holy-croſs, or Holy-well, given to them by king Henry III., at the inſtance of ſir John Haudlo. At the ſuppreſſion, the ſcite was ſold to the duke of Suffolk, from whom it was purchaſed by Mrs. Wadham, and the college which retains her name erected thereon.

The *Dominican, Preaching*, or *Black Friars*, in the firſt year of their arrival in England, A.D. 1221, built a houſe and a chapel in the pariſh of St. Edward, on a plot of ground given them by Iſabel de Balbec, widow of Robert, earl of Oxford. This place, however, afterwards proving too confined for them, they removed, about 40 years after, to a ſmall iſland near the Watergate, where they continued to reſide till the diſſolution.

The *Franciſcan* or *Grey Friars* had their houſe in the pariſh of St. Ebb. The chief founder and benefactor of this eſtabliſhment was H. III. It was granted, 36 H. VI., to Richard Andrews and John Howes.

The *Carmelite* or *White Friars* firſt ſettled in Oxford A.D. 1254, in a houſe given them by Nicholas de Meules near the river, oppoſite to Rowley. About 60 years afterwards, however, they were transferred by king Edward II. to the ancient palace of Beaumont, which they poſſeſſed till the ſuppreſſion.

The *Crouched* or *Croſſed Friars* firſt fixed their habitation in Grantpoint, near Broadgate-hall; but about the year 1348, they procured a houſe and chapel in the vicinity of the church of St. Peter's in the Eaſt.

The houſe of the *Friars-de-Sacco*, or *de penitentia Jeſu*, ſtood near the Weſt-gate, on the ſcite of the very ancient church of St. Benedict or Burdoc. Theſe friars were ſuppreſſed, with ſome other mendicant orders, A.D. 1307, when the houſe and its appurtenances were beſtowed on the Grey friars.

Trinity Houſe was founded by Edmund, earl of Cornwall, in 1291, for the reception of "Trinitarian friars of the redemption of captives," who reſided here, and in the chapel of the Holy Trinity within Eaſt-gate, till nearly the time of the general diſſolution.

The *Palace of Beaumont* above mentioned, as beſtowed on the Carmelite friars, ſtood on the weſt ſide of the city. It was built by Henry I. before the year 1128, and continued to be a favourite regal reſidence during ſeveral ſucceeding reigns. Henry II. ſpent much of his time in this palace, which had the honour of giving birth to his gallant ſon, Richard I. All the buildings were pulled down at the diſſolution except the hall, the materials of which were afterwards uſed by archbiſhop Laud, in his additions to St. John's college. Only a ſmall low fragment of them, therefore, now remains, and this appears to have conſtituted a part of one of its inferior diviſions.

The *Caſtle*, built, or, as King ſuppoſes, reſtored, by Robert de Oigli, was a fortreſs of prodigious ſtrength, and occupied a great extent of ground cloſe to the river Iſis, towards the weſtern ſide of the city. Being in a neglected ſtate, and much decayed in the reign of Charles I., it was repaired and rendered a poſt of defence by that monarch; but after it became poſſeſſed by the parliament, a great part of its buildings were demoliſhed. Hence the only remains of it now in exiſtence are the mount, a crypt, and the ſhell of one of the original towers, which is a ſquare, maſſive ſtructure, lighted by a few loop-holes only, and having a projecting baſtion turret at one angle, through which a narrow ſtair-caſe leads to the top of the caſtle. It now conſtitutes part of the gaol.

Eminent Natives of Oxford.—Though this city has been for ſo many ages the ſeat of learning, and "nurſery of talents," it does not appear to have given birth to many eminent or illuſtrious characters. Beſides Richard I., we do not find the names of any very conſpicuous perſonages ranked among the native "worthies" of this city. The following perſons, it is believed, conſtitute nearly the whole number: Thomas Cowper, biſhop of Wincheſter, Thomas Harriot, who invented the preſent mode of notation in algebra, the Rev. William Chillingworth, ſir William D'Avenant, Dr. Charles D'Avenant, his ſon, Dr. Edward Pococke, Anthony A. Wood, (ſee a very ample memoir of him in "Athenæ Oxonienſes," 4to. 1813,) ſir Matthew Wright, Barten Holyday, William Joyner or Lyde, Gerard Langbane, author of an account of the Engliſh dramatic poets, Samuel Welles, and Dr. Edward Wootton.

The preceding account of Oxford has been derived from perſonal knowledge of the city, and from ſeveral publications of the beſt authority; but it is regretted that the nature of the preſent work will not admit of a more copious narration. The chief books conſulted are "The Hiſtory and Antiquities of the Univerſity of Oxford," by Anthony A. Wood, M.A., edited and much enlarged by John Gutch, M.A., in 5 vols. 4to., publiſhed in the years 1786, 1790, 1792, and 1798. This work contains a large maſs of information, the moſt eſſential facts in which, with the addition of much biographical and critical materials, are introduced into "A Hiſtory of the Colleges, Halls, and public Buildings attached to the Univerſity of Oxford, including the Lives of the Founders, by Alexander Chalmers, F.S.A.," 2 vols. 8vo., 1810. The author of this intereſting work promiſes, in his introduction, "to enter more fully into the hiſtory of the univerſity, from the earlieſt times." "The Oxford Univerſity Calendar for the year 1813," 12mo., is an entirely new publication, and is a very uſeful and intereſting vade mecum. "The Oxford Guide," or "Companion," is a ſuperficial little volume, and unworthy of this learned city. It was ſatirized by T. Warton, in "A Guide to the Companion, and Companion to the Guide." "Oxoniana," 4 vols., 12mo., contains many curious anecdotes relating to the univerſity, city, and to perſons connected with both. In The Beauties of England, vol. xiii., Mr. Brewer has given a very judicious epitome of the hiſtory of Oxford, with accounts of all the principal places in the county. "The Hiſtory of the Univerſity of Oxford, with 80 coloured Engravings," to be completed in 2 vols. 4to., is an elegant work now publiſhing in monthly numbers. The following publications contain much valuable and uſeful information reſpecting different colleges: Wood's Athenæ Oxonienſes, a new edition of which is now printing under the careful and able editorſhip of Philip Bliſs, fellow of St. John's college; Churton's Lives of the Founders of Brazen-noſe College; Lowth's Life of William of Wykeham, founder of New College; Warton's Life of Sir Thomas Pope, Founder of Trinity College; Chandler's Life of William Waynflete, Founder of Magdalen College; Spencer's Life of Henry Chichele, Founder of All-Souls College.

OXFORD, a townſhip of America, in Worceſter county, Maſſachuſetts; 11 miles S. of Worceſter, and containing 1237 inhabitants.—Alſo, a town taken from the north part of Derby, in Connecticut, 17 miles N.W. of New Haven; containing 1400 inhabitants.—Alſo, a poſt-town of New York, in Chenango county, between Jericho and Norwich;

incorporated in 1793, and containing an incorporated academy, and 1405 inhabitants.—Alſo, a townſhip of New Jerſey, in Suſſex county, on the E. bank of Delaware river, 15 or 20 miles N.E. of Eaſton, in Pennſylvania, containing, in 1790, 1905 inhabitants.—Alſo, a townſhip of Pennſylvania, in Philadelphia county; containing 1518 inhabitants.—Alſo, a townſhip in Grenville county, upper Canada, ſituated in the rear and to the northward of the townſhips of Edwardſburg and Auguſta, and watered by the Radeau.—Alſo, a townſhip upon the Thames, in the weſtern diſtrict, Upper Canada, S. of Dundas-ſtreet, where the weſtern end of that road meets the upper forks of the river Thames.—Alſo, a town in New Hampſhire, Grafton county, containing 988 inhabitants.—Alſo, a town called Upper Oxford, in Cheſter county, Pennſylvania, having 620 inhabitants.—Alſo, a port of entry, on the E. ſhore of Cheſapeak bay, in Talbot county; 13 miles S. by W. of Eaſton, and about 48 S.E. of Baltimore.—Alſo, a ſmall poſt-town of North Carolina; 36 miles from Hillſborough, and about 416 from Philadelphia.

OXFORDSHIRE, one of the central counties of England, is bounded by Glouceſterſhire on the weſt; by Buckinghamſhire on the eaſt; by Berkſhire on the ſouth, ſouth-weſt, and ſouth-eaſt; by Northamptonſhire on the north; and by Warwickſhire on the north-weſt. In figure this county is extremely irregular, being only ſeven miles in breadth in the centre, while its ſouthern diviſion is about twelve miles in diameter, and its northern half varies from little more than a mile, to thirty-eight miles in width. This latter portion, in proceeding northward from the centre, aſſumes the form of a cone, which terminates at what is denominated the Three-ſhire ſtone, in a complete point or apex. The total area of the county is computed, by Mr. Davis, at 742 ſquare miles, or 450,000 acres, of which 309,000 lie to the north, and 141,000 to the ſouth-eaſt of Oxford; but in the table of poor rates drawn up under the inſpection of the right honourable George Roſe, the number of acres is eſtimated at 474,880.

Hiſtorical Events.—When the Romans obtained poſſeſſion of Albion, Oxfordſhire, with ſome portion of the county of Glouceſter, conſtituted the dominions of a Britiſh tribe called the *Dobuni*, who, according to Camden, derived their name from the word *Duffen* or *Dwfn*, which ſignifies deep, or low; becauſe inhabiting a plain or valley encompaſſed with hills. Other writers, however, ſuppoſe their appellation to be a compound of the terms *dob*, a ſtream, and *en*, land; in alluſion to their reſidence in the vicinity of the river Iſis or Thames. The Dobuni ſeem to have been of a leſs warlike diſpoſition than moſt of their neighbours. Before the arrival of the Romans, they were held in ſubjection by the Cattieuchlani, whoſe domination was ſo galling, that the Dobuni immediately embraced the protection of the new invaders, and were admitted as tributary allies of the Roman people. Hence Cogidumnus, their legitimate prince, was not only continued in the government of his own territories, but had other ſtates placed under his authority. The ſame power and privileges deſcended to his ſucceſſors, each of whom, in union with his ſubjects, evinced on all occaſions a firm adherence to their illuſtrious ſuperiors, during the whole period of the reſidence of the Romans in Britain.

But though the Dobuni yielded thus eaſily to the yoke of Rome, they diſdained to bend without a valiant reſiſtance to the treacherous Saxons, whom their king unhappily concurred in inviting to England, to aſſiſt in repelling the invaſions of the northern barbarians. Theſe, on the contrary, they oppoſed with as much firmneſs and reſolution as animated the inhabitants of any other diſtrict, and were indeed among the laſt of the Britons who could be brought to ſubmit to the Saxon dynaſty. When this event happened, however, and the heptarchy was fully eſtabliſhed, Oxfordſhire became part of the powerful kingdom of Mercia, and remained annexed to that monarchy to the lateſt period of its independence. During this era, Dorcheſter was made the ſeat of a biſhop's ſee, afterwards removed to Lincoln, in the reign of William the Conqueror. The name Dobuni was at the ſame time loſt, and that of Wiccii applied to the inhabitants of the whole diſtrict which that tribe had formerly poſſeſſed.

Towards the end of the ninth century, when the Danes firſt penetrated into Mercia, they fixed their head-quarters for ſome time at Reading, in Berkſhire, and ravaged all the ſouth-eaſtern part of the county of Oxford. On this occaſion little oppoſition appears to have been made to their inroads by the Wiccii; but in the ſubſequent conteſts which enſued between the Danes and the Saxons, ſeveral very obſtinate and furious engagements were fought within the limits of Oxfordſhire. Hoke-norton is remarkable for a dreadful ſlaughter of the Kentiſh diviſion of the army of Edward the Elder, by the Danes, and the Five Burgher inſurgents under the command of Ethelwald. The victory, however, was dearly purchaſed, and Ethelwald having fallen, Edward had the ſatisfaction of finding himſelf freed from a dangerous competitor.

In the wars between the houſes of York and Lancaſter, ſeveral perſons of eminence belonging to this county loſt their lives and properties; but it had the good fortune to eſcape the deſtructive ravages, which at this period deſolated many other diſtricts of the kingdom. In one inſtance only did the partizans on either ſide enter Oxfordſhire in arms. This was in the year 1469, when the earl of Warwick took poſt near Banbury, and ſoon after completely overthrew the Yorkiſts, under the command of the earl of Pembroke, whom he took priſoner, and thus paved the way for the temporary reſtoration of Henry VI. The ſcene of this deciſive action was the plain called Daneſmore, on the border of the county.

Oxfordſhire, however, was not ſo much favoured during the next great civil conteſts, which divided the people of England, and deluged her fertile fields with the blood of her own citizens; for though the inhabitants do not ſeem to have embraced with ſenſeleſs zeal either the republican or the royal cauſe, it was their calamity to feel the iron rod of war with peculiar ſeverity. The contending armies frequently traverſed the county from one extremity to the other, levying contributions, and committing exceſſes equally deſtructive to the great body of the people, whether the troops in poſſeſſion marched under the banners of the king, or of the parliament.

General Aſpect, Soil, and Climate.—Oxfordſhire exhibits conſiderable variety of aſpect. In its ſouthern diviſion, an alternation of hill and dale is productive of many pleaſing diſplays of pictorial ſcenery. The Chiltern hills, partly clothed with wood, and ſometimes arable, almoſt to their ſummits, poſſeſs a rich diverſity of appearance. The middle diſtrict of the county is deſtitute of this inequality of ſurface ſo favourable to beauty, but it is well wooded and highly fertile. In proceeding more to the north the ſame flatneſs prevails, and as the fields are generally incloſed by ſtone fences, the eye "is often fatigued by a rude and frigid monotony of ſcene."

The ſoils of Oxfordſhire are divided by Mr. Young, in his Agricultural Survey, into four different claſſes, of which, he obſerves, three are ſo marked by nature, as to allow of little doubt reſpecting them. Theſe are the Redland, the

Stonebraſh, and the Chiltern. The Redland abounds chiefly in the northern diſtrict, and is certainly the beſt ſoil in the county. "It is deep, ſound, friable, yet capable of tenacity; and adapted to every plant that can be truſted to it by the induſtry of the cultivators." The extent of land in which this ſoil prevails is 79,635 acres. The Stonebraſh diſtrict is more extenſive, and includes the greater part of the middle diviſion of the county. It is eſtimated to contain 164,023 acres, almoſt the whole of which is incloſed. The predominant feature of this tract is a "ſurface of greater or leſs depth, of a looſe, dry, friable ſand or loam, apparently formed of abraded ſtone, and abounding with many fragments of it." It is excellently adapted for turnips, and is likewiſe calculated for the culture of wheat. The Chiltern diſtrict to the ſouth conſiſts of 64,778 acres of a ſandy loam, of more or leſs depth, intermixed with flints, and reſting on a bed of chalk, which is in ſome places very white and pure, but in others imperfect, and in all containing a great proportion of calcareous earth. The other ſoils in the county are ranged under the general appellation of "miſcellaneous loams," which are calculated to occupy 166,400 acres. They include all ſorts of ſoil, from looſe ſand to heavy clay.

The *climate* of Oxfordſhire, as may be ſuppoſed, is conſiderably affected by the ſurface varieties we have juſt mentioned. In the northern diviſion, where the country is incloſed principally by ſtone fences, and where plantations are ſcanty, the air is generally cold and piercing during the greater part of the year, and exceſſively hot in the ſummer months. It is cold, alſo, throughout the whole Chiltern diſtrict, eſpecially on the poor chalk lands, at the foot of the hills, where it is remarked that the froſt will take effect ſooner, and continue longer, than on the deeper lands in the vicinity. In warm ſeaſons, the ſame diſtrict is uſually moiſt, owing to the fogs, which are more frequent on the hills and woods than in the vales.

Mineralogy —Oxfordſhire poſſeſſes little to boaſt of in a mineralogical eſtimate. Dr. Plot, indeed, ſuppoſes that a ſilver mine was wrought formerly in the Chiltern diſtrict, but this opinion we are inclined to regard rather as an hypothetical concluſion, than the reſult of obvious deduction. At preſent no metal whatever is found in any part of the county. Freeſtone quarries, however, are frequent, and both limeſtone and ſlate are plentiful. Near Shotover is a conſiderable quantity of ochre, which the learned naturaliſt abovementioned characteriſes as "the beſt of its kind in the world, being of a true yellow colour, and very weighty." The clays in the neighbourhood of Oxford were anciently uſed by potters with ſome ſucceſs, but their quality is very inferior for the purpoſes of pottery to the clays of Staffordſhire, and the manufacture has been long diſcontinued.

Rivers.—No county in England is more plentifully ſupplied with rivers than that of Oxford. Dr. Plot ſays there are no leſs than ſeventy diſtinct ſtreams, which either take their riſe in this county or flow through it, nor do we believe the number is at all exaggerated, though at the ſame time it muſt be admitted that only a few of them are entitled to the denomination of conſiderable rivers. The principal of them are the Thame, the Iſis, the Charwell, the Evenlode, the Glym, the Ray, and the Windruſh. The whole of theſe rivers unite with each other at different points of the county, and eventually conſtitute the Thames or Thamiſis. The chief branch of this river enters Oxfordſhire, under the denomination of the Iſis, at Kelmſcot, and proceeds in an irregular channel by Tyneſham, Godſtow, Oxford, and Abingdon, in Berkſhire, to Dorcheſter, where it is joined by the Thame, and is then called the Thames. Thence it continues its courſe by Wallingford, Goring, Whitchurch and Caverſham, to Henley, near which town it paſſes into Buckinghamſhire. Throughout the whole of its current by Oxfordſhire this river forms the boundary between it and the county of Berks, and exhibits in the ſcenery of its banks much variety and beauty of aſpect.

Tenures, Eſtates, &c.—The tenures, by which the landed property of Oxfordſhire is held, are analogous to thoſe moſt common in all the ſouthern counties of England. Freehold and copyhold leaſes for lives are prevalent, but more particularly church and college leaſes, both for lives and for a certain term of years. The uſual fine is one year and a half's rent. Eſtates of courſe vary greatly in extent. Some few noblemen and gentlemen have very large poſſeſſions here. Theſe, with the eſtates belonging to the church, and different corporate bodies in the univerſity, occupy a great proportion of the landed property of the county. There are, however, many middling proprietors and ſome of a ſmaller claſs. A few of the former, and almoſt all of the latter, cultivate their own grounds, and, generally ſpeaking, appear to live in a reſpectable and comfortable manner. The price of land here is averaged by Mr. Turner at 26 years' purchaſe.

Leaſes, Size of Farms, Rents, Tithes, &c.—Oxfordſhire, notwithſtanding all the advantages of learning it poſſeſſes, muſt be ranked among thoſe counties in which the leading principles of agricultural proſperity are either miſunderſtood, or neglected from falſe and intereſted motives. The ſyſtem of leaſes, ſo decidedly favourable to the improvement of property, is here almoſt totally neglected; and even in thoſe caſes where leaſes are granted, their duration is limited to ſo ſhort a period as to render them of little avail. From this general remark, however, a few gentlemen ought undoubtedly to be excepted, who uſually grant leaſes for fourteen or twenty-one years, upon a decided conviction of the utility of the practice, which it is wonderful any individual ſhould queſtion. "Let all England," ſaid one of theſe gentlemen juſtly to Mr. Young, "be farmed without leaſes, and tithe every where taken in kind, and England from that hour ſtarves." The ſubject, therefore, is important, and deſerves the moſt ſerious attention; for the plan of no-leaſes, being at once injurious to the cultivator and to the landlord, muſt conſequently retard the national proſperity.

Farms in this county differ conſiderably in extent, but they are moſtly inferior in ſize to thoſe in the other counties of England. In the foreſt diviſion there are few farms which pay more than 20*l.* a-year of rent. In the rich Thame diſtrict they ſeldom exceed 300 acres. About Stoken-Aſh there are none capable of maintaining more than 200 or 300 ſheep. For ſome miles round Blenheim, farms are in general from 100 to 500 acres, here and there a larger, and ſome ſmaller. Rents are thus averaged by Mr. Young; Redland 30*s.*, Stonebraſh 20*s.*, Chiltern 16*s.*, and miſcellaneous loam 25*s.*; ſo that the average of the whole county is 22*s.* 10*d.* *per* acre, and its entire rental about 543,297*l.* 1*s.* 6*d.* This average, however, is probably ſomewhat increaſed ſince the date of that gentleman's report in 1807.

Tithes are of different deſcriptions in this county. Some rectors have one in fifteen and ſome one in twenty only. The average of commutation for arable land fairly let, is one-fourth of the rent. On other grounds, however, it is much lower.

Agriculture.—Notwithſtanding the diſadvantageous circumſtances above-mentioned, it is but juſtice to the Oxfordſhire farmers to remark, that the practice of agriculture has made rapid ſtrides in improvement within the laſt century.

The

The ſyſtem of common field huſbandry has been gradually ſinking in repute, and the whole county is now nearly incloſed. The rotation of crops varies according to the ſoil. In the Redland diſtrict the uſual courſe is 1, turnips; 2, barley or ſpring wheat; 3, clover; 4, wheat; 5, beans or peas; 6, oats. On the Stonebraſh lands; 1, turnips; 2, barley, with clover, rye graſs, or trefoil, or mixed; 3 and 4, clover, &c. as above for one or two years; 5, wheat, on once ploughing; 6, oats, peas, or beans; 7, ſainfoin. In the Chiltern diſtrict the courſe is nearly ſimilar: 1, turnips; 2, barley; 3, clover, or trefoil and ray-graſs; 4, wheat, and 5, oats, barley, peas, or vetches. Among the crops only partially cultivated here are lentils, rape, cabbages, carrots, potatoes and chicory. Rhubarb is ſtill alſo grown near Drayton, but the culture of hemp, flax, and hops, (all of which uſed to be raiſed in conſiderable quantities,) is now almoſt entirely neglected.

From the number of its rivers Oxfordſhire abounds in meadows and paſtures; but theſe are no longer, as in the time of Gibſon, the "greateſt glory" of the county, being much circumſcribed by the encroachments of arable cultivation. A large tract of meadow land, on the banks of the Charwell, has been greatly injured by the conſtruction of the canal from Oxford to Banbury. At Water Eaton is the beſt graſs land in the county. It is under dairies which indeed conſtitute the appropriation of moſt of the meadow and paſture grounds in Oxfordſhire. Butter is the chief article made, only a ſmall proportion of cheeſe being made for ſale. The long horned breed of cows is that generally preferred here. In the middle parts of the county a few oxen, cows and ſheep are fatted; and a number of calves are ſuckled for the London market. No watered meadows are found in Oxfordſhire, though many places are extremely well adapted for their formation.

Foreſts, Woods, and Plantations.—Oxfordſhire is ſaid by Camden to have been anciently famous for its woods; and even at preſent, except in the more northerly parts, it is better ſupplied with trees than moſt other counties of England. The only foreſt, however, within its boundaries, is that of Whichwood, which comprehends 6720 acres, 1 rood, and 39 poles. In this foreſt, the oak, the aſh, the beech, and the elm, are intermixed; but the oak is moſt abundant and thriving, and, in the courſe of half a century's growth, will be perfectly fitted for naval purpoſes. The Chiltern diſtrict is profuſely covered with beech, produced almoſt entirely by the falling of the beech maſt, very little being permitted to grow on the old ſtools. Some have ſuppoſed this diviſion of the county formed part of the great foreſt, deſcribed by Leland as ſtretching 120 miles weſtward from the borders of Kent. This opinion, however, is merely conjectural, though in ſome degree plauſible.

The other principal wood-lands in this county are thoſe at Stanton-St.-John, called the "Quarters," and at Blenheim, the ſeat of the duke of Marlborough. Smaller plantations are numerous: almoſt every gentleman's ſeat in Oxfordſhire being more or leſs ſurrounded with trees of different ages and ſorts.

Waſte Lands.—The only tracts of waſte land, of any very conſiderable extent, are thoſe ſituated in the purlieus of Whichwood-foreſt, and the deanery diſtrict, termed Ottmoor, which lies in the vicinity of Iſlip. The laſt, which contains about 4000 acres, is commonable to eight adjoining townſhips. The whole of it is extremely flat and wet, and conſequently unwholeſome to cattle, as well as prejudicial to the neighbourhood. The ſoil, however, is good, and if drained, (which might be eaſily effected,) and incloſed, would undoubtedly prove highly amenable to the purpoſes of agriculture. The value of the grounds would thereby increaſe to probably ten times their preſent amount. The ſame may be ſaid of the waſte lands of Whichwood, and of the ſmall commons in the northern diſtrict; but thoſe in the Chiltern diviſion are not ſuſceptible of much culture.

Roads and Canals.—The roads of Oxfordſhire, till within theſe laſt few years, were deplorably bad. Young, in his "View of the Agriculture" of this county, obſerves that, 40 years ago, "the high roads were in a condition formidable to the bones of all who travelled on wheels." The ſame writer alſo characteriſes the croſs roads as impaſſable at that period, without real danger. Now, however, a great improvement has taken place: good turnpike roads interſect the county in the direction of all its market-towns, and the greater part of the parochial and croſs-ways are improved in a proportional degeee.

The only *canal* yet cut through any portion of Oxfordſhire is that which enters the county at its northern extremity, between Claydon and the Three-ſhire-ſtone. "Approaching the vicinage of the river Charwell at Cropredy, it proceeds at a ſmall diſtance from the banks of that river to the city of Oxford, (whence it is called the Oxford canal,) where its channel terminates, and is ſucceeded by the navigation of the Iſis." The probable advantages which will accrue from this cut are very great, as a direct water communication has been thereby opened between the interior of the county, and Birmingham, Liverpool, Mancheſter, and the Wedneſbury collieries, as well as with the cities of London and Briſtol.

Civil and Eccleſiaſtical Diviſions.—Oxfordſhire is divided into fourteen hundreds, which together contain 1 city, 12 market-towns, and 207 townſhips and pariſhes, all of them in the dioceſe of Oxford, and province of Canterbury. According to the parliamentary returns of 1811, the number of houſes in the whole county was 23,217, and the number of inhabitants 119,191. In 1801, the houſes were eſtimated at 20,599, and the population at 109,620 perſons. Oxfordſhire is repreſented in parliament by nine members; two knights of the ſhire, two citizens for Oxford, two repreſentatives for the Univerſity, two burgeſſes for Woodſtock, and one for Banbury.

Manufactures.—Hitherto, at leaſt, Oxfordſhire has had little claim to be ranked among the number of the manufacturing counties of England. Its articles of manufactured produce are neither numerous nor of great importance. Witney blankets, indeed, were formerly much noted; but this branch of trade is now declined, and the town is reduced to a comparatively poor and deſtitute condition: for though the introduction of machinery has revived, in a ſmall degree, the buſineſs of the maſters, that circumſtance has not contributed to the benefit of the labouring poor. At Woodſtock is a ſmall manufacture of poliſhed ſteel articles, which was introduced by a Mr. Medcalfe, and was at one time in a very flouriſhing ſtate. Here is likewiſe a manufacture of leather breeches and of gloves, which employs about 70 men, and 1400 or 1500 women and girls. The wages of the men are from one guinea to 30*s.* weekly, and thoſe of the women from 8*s.* to 12*s.* *per* week. A ſmall quantity of lace is made in the town and neighbourhood of Thame; and at Bloxham and Banbury a coarſe ſort of velvet is produced. Henley has, for ſeveral centuries, been one of the London depots for malt.

Antiquities.—Oxfordſhire certainly does not offer ſuch a field for antiquarian reſearch as many other counties; but, nevertheleſs, it affords ſome materials in this branch of inquiry, by no means unworthy of attention. Several very curious Britiſh coins have been found within its limits, and there

there are numerous barrows and other monuments here, which, we preſume, may properly be referred to an era antecedent to the records of hiſtory. Of this deſcription is the Druidical monument, called *Rollrich*, or *Rowlright Stones*, which were originally 60 in number, (though only 22 of them are now ſtanding,) and formed a circle nearly equal in diameter to the outer one at Stonehenge. The ſizes of theſe ſtones, however, are trifling, compared to the immenſe maſſes of the Wiltſhire temple, few of them exceeding four feet in height, and ſixteen inches in breadth. One only, in the northern part of the circle, is ſeven feet high, and five and a half broad; but detached is another, meaſuring eight feet in height, and ſeven in breadth. This laſt is denominated the King-ſtone, from a tradition that ſome ancient monarch and his court were converted into ſtones on this ſpot. Contiguous to it is a large long barrow, ſuppoſed to contain the aſhes of an arch-druid; and near it is a ſquare entrenchment, with a double ditch and vallum, having ſome remains of ſtone-work in its interior. Theſe Dr. Stukeley calls Druid-courts, or houſes. Several other barrows, with the apparent foundations of buildings cloſe to them, are diſcovered in the vicinity of this temple; and about 300 paces from it was formerly a kiſtvaen of ſix ſtones, which have been lately removed. See KISTVAEN.

Owing to the continued amity which exiſted between the inhabitants of this diſtrict and the Romans, the relics of Roman military poſſeſſion are few. No doubt, however, that celebrated people had ſeveral ſtations in Oxfordſhire, of which the principal was at Aldcheſter or Alceſter. Dorcheſter and Swalcliff are likewiſe ſuppoſed to have been Roman towns, or poſts, of conſiderable importance. Coins of the emperors, and fragments of teſſellated pavement, are frequently dug up, and there are a few ſmall encampments and funeral mounds diſperſed throughout the county, which are alſo probably of Roman origin. Of theſe laſt, the moſt remarkable is that termed Aſtal barrow, which borders on the Old Akeman road, and which is conjectured by Dr. Plot to be the ſepulchre of ſome diſtinguiſhed leader, on account of its uncommon height and circumference. Of the four principal Roman roads interſecting the iſland, one only paſſes through Oxfordſhire. This is the Ikenild-ſtreet, which enters the county at the pariſh of Goring, and croſſes it in a direction from ſouth-weſt to north-eaſt by Iſpden, Ewelm, Watlington, and Crowell, to Chinnor, where it enters Buckinghamſhire. Vicinal ways, however, are abundant. The Akeman-ſtreet ſtretches itſelf throughout the broadeſt part of the county, entering it near Holywell, and leaving near Ambroſden, in the vicinity of the ſtation Alceſter. From this ſtreet many minor roads branch off in different directions. Two of theſe are traced near Kirklington, a third within Blenheim-park, and a fourth to the ſouth of Biceſter. Between Mongewell and Nuffield is a vallum, or high ridgeway, called Grimes-dyke, or Devil's-ditch, alſo numbered by Dr. Plot among the Roman vicinal ways, but we are inclined to refer it to a more remote era. This embankment is ſtill very high, and has in ſome places a ſingle, and in others a double agger.

The moſt eminent places in the county, during the government of the Saxons and Danes, were Banbury, Benſington, Birenceſter or Biceſter, Burford, Thame, Chipping-Norton, Bampton, Woodſtock, and Iſlip. The two laſt were royal vills. King Edward the Confeſſor was born at Iſlip; and Woodſtock afterwards became famous as a palace of the monarchs of the Norman dynaſty. Several Saxon and Daniſh encampments may likewiſe be traced within the limits of this county, particularly at Caſtleton, Adwell, and Chipping-Norton.

After the Conqueſt, king William ordered a number of caſtles to he erected in this county, as in moſt others in England, with the view of enſuring the ſubmiſſion of his new ſubjects. Of theſe fortreſſes, the principal in Oxfordſhire were the caſtles of Oxford, Bampton, Banbury, Deddington, Ardley, and Middleton, all of which were places of great ſtrength, and ſtill retain marks of their former extent and conſequence as military poſitions. A few fortifications of a much later period are alſo met with in different diſtricts of the county.

As a ſubject of antiquities, we ſhall conclude this article with a ſhort liſt of the various religious houſes which have exiſted in Oxfordſhire, whether before or ſince the arrival of the Normans, excepting only thoſe already mentioned in our deſcription of Oxford. They are as follow:

1. A college at Banbury, dedicated to St. Mary, and endowed with 48*l.* 6*s.* *per annum*.

2. An hoſpital in the ſame town, dedicated to St. John, for the reception of lepers.

3. A Ciſtercian abbey at Bruerne, founded by Nicholas Baſſet, A. D. 1147.

4. A monaſtery for Auſtin canons at Biceſter, founded by Gilbert Baſſet, baron of Hedingdon, A. D. 1182.

5. An hoſpital, at the ſame place, founded A. D. 1355.

6. An hoſpital, or priory, at Burford, dedicated to St. John.

7. An Auſtin cell to the abbey of Nottely, at Caverſham.

8. An alien priory, at Charlton, cell to the abbey of St. Ebrulf at Utica, in Normandy.

9. A Gilbertine priory at Clattercote, dedicated to St. Leonard. It was for ſome time an hoſpital for lepers.

10. An alien priory of Black monks at Cogges, cell to the abbey of the Holy Trinity at Fiſchamp in Normandy. It was founded about the year 1100.

11. An hoſpital at Crowmarſh, founded for ſick brethren, A. D. 1248.

12. The cathedral church at Dorcheſter, was eſtabliſhed about the year 635, by Birinus, firſt biſhop of that ſee.

13. An abbey for black canons of the order of St. Auguſtine, at the ſame place, founded by Alexander, biſhop of Lincoln, A. D. 1140.

14. A Benedictine abbey at Eynſham, built and endowed by Ailmer, earl of Cornwall, before A. D. 1005.—Reſtored by Robert Bloet, biſhop of Lincoln, in the reign of Henry I.

15. An hoſpital at Ewelme, founded and endowed by William de la Pole, earl of Suffolk, for two chaplains and thirteen poor men. A. D. 1437.

16. A Benedictine nunnery at Godſtow, built A. D. 1138, by Editha or Ediva, a religious matron, aſſiſted by the contributions of other pious perſons. The conſecration of this abbey was performed in the preſence of king Stephen, his queen, and a vaſt concourſe of prelates and nobility. The celebrated Roſamund Clifford, miſtreſs to Henry II. was buried here.

17. A priory of nuns of the order of St. Auſtin, at Goring, founded temp. Hen. II.

18. A houſe for ſiſters of the order of St. John of Jeruſalem, at Gosford, founded ſoon after the Conqueſt; but removed in 1180.

19. A priory of Benedictine nuns at Littlemore, founded temp. Hen. II. Suppreſſed and given to cardinal Wolſey, A. D. 1524.

20. An alien priory of Benedictines at Minſter Lovel, a cell to the abbey of St. Mary de Ibreio, or Iri.

21. A Bene-

21. A Benedictine cell at Milton to the monaſtery of Abbington.

22. An Auſtin priory at Norton, built by William Fitz-Alan the ſecond, temp. Hen. II.

23. A houſe for knights templars at Saundford, founded about temp. Stephen.

24. A Benedictine nunnery at Stodley, built and endowed by Bernard de Walerico, in the reign of Henry II.

25. A Ciſtercian abbey at Thame. This ſociety was originally founded at Otteley, in the pariſh of Oddington, by ſir Robert Gait, but was ſhortly after removed hither. Alexander, biſhop of Lincoln, gave the ground on which this monaſtery was built, A. D. 1137.

26. An hoſpital alſo in this town, founded by Richard Quatermain, either in the reign of Henry VI., or of king Edward IV.

27. A houſe of Trinitarian friars at Thuſfield, or Thuffield, founded before 33 Edw. III.

28. An hoſpital of St. Mary in Woodſtock.

29. A priory of Auſtin canons at Uroxton, founded in the beginning of the reign of king Henry III. by Michel Belet. Granted to ſir Thomas Pope. [Camden's Britannia, by Gough, 3 vols. folio. Beauties of England and Wales, vol. ix. by J. N. Brewer. Natural Hiſtory of Oxfordſhire, by Robert Plot, LL.D. Oxford, edit. 1677. Tanner's Notitia, fol. Magna Britannia. View of the Agriculture of Oxfordſhire, by Arthur Young, ſecretary to the Board of Agriculture, 8vo. London, 1809.]

OXGANG, or OXGATE *of Land*, is ordinarily taken, in our old law-books, for fifteen acres; being as much land as it is ſuppoſed one ox can plough in a year.

"Bovata terræ, *q. d.* quantum ſufficit ad iter vel actum unius bovis."

In Lincolnſhire they ſtill corruptly call it *oſkin* of land. This term is uſed in Scotland for a portion of arable land, containing thirteen acres.

OXHANGER, in *Geography*, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63° 19′. E. long. 21° 58′.

OX-HARROW, in *Agriculture*, a term applied to a very large ſort of harrow, called in ſome countries a drag.

OXIANA, in *Ancient Geography*, a town of Aſia, in Sogdiana, near the *Oxus*; which ſee.

OXIANA *Palus*, a marſh of Sogdiana, called by Pliny Oxus, from the name of the river of which it is the ſource.

OXIBII, a people of the Maritime Alps, between the river Argens and Antibes. Theſe people were powerful, and ſignalized themſelves againſt the Romans, when they undertook the conqueſt of the Gauls. They leagued with the Deciales, for attacking the towns of Nice and Antibes. Steph. Byz. aſſigns to them a town called "Oxibium." Strabo mentions a port named "Oxibus" as belonging to them, ſuppoſed to be the ſame with the maritime town called by Polybius "Ægytna."

OXNA, in *Geography*, a ſmall iſland on the E. coaſt of Shetland. N. lat. 60° 8′. W. long. 1° 52′.

OXNAY, a river-iſland of England, in the county of Kent, formed by the divided ſtreams of the Rother, about ſeven miles long, and three broad, containing three pariſhes, and giving name to a hundred.

OX-SHOEING MACHINE, in *Agriculture*, a ſimple contrivance employed by Mr. Young, in executing the buſineſs of ſhoeing theſe animals. It is brought to the attention of the public, in the twenty-ſixth volume of his Annals, where he mentions that it is now almoſt twenty years that he has been in the habitual practice of uſing oxen for both plough and cart, and from the beginning was averſe

from making any trials by *caſting* them for ſhoeing. The late lord Nugent uſed many at Goſfield, in Eſſex, and from his machine for this purpoſe, he took the idea of his preſent one, which is repreſented in the *Plate Ox-Shoeing* (*Agriculture*,) *figs.* 1 and 2; but the ſtumps for the fore-legs, and the moveable roller for the hind ones, he has added ſince, as well as altered the head apparatus, and added the hinder ſtrap.

a, is the top-piece of the ſliding-plank, to ſink down and confine the head.

b, *b*, are broad ſtrong ſtraps of leather, faſtened by links of iron, to prevent the ox from lying down on his belly, which they are apt to do; and the hinder ſtrap is to prevent his drawing back to the injury of his head and neck.

c, *c*, are two ſtumps, ſtrongly fixed in the ground, to tie the fore-legs to.

d d, is an iron that lets up and down, to confine the roller to which the hinder legs are tied for ſhoeing.

e, *e*, *e*, are holes (with others correſponding not ſeen in the plate) for the roller to be ſhifted according to the length of the ox.

It is ſuggeſted that the whole is ſo ſimple, that it is preſumed any country carpenter may be able to build it without any difficulty, from inſpecting the plate.

And it is well remarked that the ſhoeing of oxen is generally ſo ill done, that the ſhoes are perpetually coming off, which is a great objection and expence. And he has never had a blackſmith that did it well, ſo that upon land not flinty or gravelly, he ſhould not ſhoe at all, if they did not go upon the high roads. Whatever improvement can, by any means, facilitate the uſe of oxen in huſbandry, deſerves much attention, the importance of ſubſtituting them for horſes riſing with the price of meat, and it is with that view he has inſerted this plate and explanation. See SHOEING *Oxen*.

OXUCIÆ, in *Natural Hiſtory*, the name of a genus of foſſils of the claſs of the ſelenitæ, but of the columnar, not the rhomboidal kind.

The word is derived from the Greek ὀξυς, *ſharp*, and κιων, a *column*; and expreſſes a body of a columnar form, and pointed or ſharp at the ends.

The ſelenitæ of this genus conſiſt of ſix equal planes, having their top or bottom no broader or more depreſſed than the others; and in this differing from the *iſchnambluces*, or flatted columnar ſelenitæ, as they do from the *iſambluces*, or *cryſtalliform*, but broken ended ones, by having their ends naturally tapering off to a point.

The bodies of this genus, like thoſe of the other genera of the columnar ſelenitæ, are liable to a longitudinal crack in their middle; and this ſometimes includes a little clay, in the form of an ear of graſs. See SELENITÆ.

Of this genus there are only two known ſpecies.

OXUS, GIHON, *Jihon*, or *Amu*, in *Ancient Geography*, a large river of Aſia, which took its riſe in the mountains of Bactriana, to the S.E. In purſuing its courſe towards the N.W., it traverſed this province, paſſed between Aria to the weſt, and Sogdiana to the eaſt; and afterwards entering into the territory of the Khoraſmii, diſcharged itſelf into the lake called the lake of Aral. See AMU.

OXWICH, in *Geography*, a ſea-port and pariſh in the cwmwd of Gwyr, cantref of Eginog (now called the hundred of Swanſea) and county of Glamorgan, South Wales, is ſituated on a ſmall promontory, to which it gives name, on the north coaſt of the Briſtol channel, at the diſtance of thirteen miles from Swanſea. A conſiderable trade in limeſtone is carried on here, and gives employment to a number of people in the vicinity. The ſea has made great encroachments on this pariſh, and is even ſuppoſed to have inundated

inundated the whole of the original village, as the old church and parſonage-houſe ſtand cloſe to the ſhore, and the preſent village is built at ſome diſtance inland. Here are the remains of a large manſion, called Oxwich caſtle, which was erected by ſir Rice Manſel, about the reign of Henry VIII. This edifice never appears to have been intended for the purpoſes of defence, but it may not unlikely have been built on the ſcite of an ancient fortreſs, as only a few yards from it there are ſtill to be ſeen the remains of a watch-tower of much older and ſtronger conſtruction. Part of this caſtle was converted, many years ago, into a farm-houſe. Lobſters and crabs are caught in great plenty along the whole coaſt of this pariſh, which, according to the parliamentary returns of 1811, contains 50 houſes, and 236 inhabitants.

Penrice-caſtle ſtands about three miles from Oxwich. It derived its name from the family of the Penrices, who ſettled here in the reign of Edward I., but is now the property of the Talbots. This demeſne has lately been amazingly improved, and exhibits a diverſity and richneſs of ſcenery altogether unexpected from the dreary appearance of the ſurrounding country. In the avenue to the gardens is a fine tomb of one of the emperors, which was brought from Italy. The village of Penrice has a good harbour for ſhipping.

North from this place, upon a mountain called Com-Bryn, is a table-like monument, or cromlech, called Arthur's ſtone. It conſiſts of ſix or ſeven ſtones, about five feet in height, ſupporting a large flat ſtone, ſuppoſed to weigh nearly 20 tons. A ſpring iſſues from beneath, which ebbs and flows with the tide, and is celebrated as "Ffynnon Vair, or my Lady's Well." Carliſle's Topographical Dictionary of Wales, 4to. 1811.

Oxwich *Point*, a cape on the ſouth coaſt of Wales, in the Britiſh channel, forming the eaſtern boundary of a bay called "Oxwich bay." N. lat. 51° 27′. W. long. 4° 6′.

OXYA, in *Botany*, a name by which many authors, eſpecially the Greeks, have called the *fagus*, or beech-tree.

OXYBAPHUS, a name contrived, as it ſeems, by L'Heritier, in one of thoſe rare monographs, of which we have mentioned ſix in our article on his life; ſee Heritier. But *Oxybaphus* and *Tricratus* are cited by Willdenow, Sp. Pl. v. 1. 185 and 187, though not to be found in the catalogue of L'Heritier's own library, nor in that of ſir Joſeph Banks. This countenances Cuvier's aſſertion, that none of his friends had all theſe diſſertations; but we cannot account for his not having had them all himſelf, and it is not impoſſible that he might merely inform Willdenow by letter of the intended preparation of theſe two. Vahl indeed quotes the monograph on the genus before us, but he might copy Willdenow. The above generic name is evidently formed from οξυς, *ſour*, or *ſharp*, and βαφευς, *a dyer*; but whether the viſcidity which covers the original ſpecies be of an acid or acrid quality, or not, no author within our reach has related, ſo that our explication is but imperfect. —Willd. Sp. Pl. v. 1. 185. Vahl. Enum. v. 2. 39. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 77. (Calyxhymenia; Fl. Peruv. v. 1. 45.)—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Nyctagines*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, with five folds, and five broad, equal, ſhallow ſegments, permanent, ſometimes three-flowered. *Cor.* of one petal, funnel-ſhaped; tube about the length of the calyx; limb ſpreading, in five equal, notched lobes. Nectary fleſhy, ſurrounding the baſe of the germen. *Stam.* Filaments three, inſerted into the nectary, thread-ſhaped, declining, rather unequal, various in length; anthers roundiſh, aſcending. *Piſt.* Germen ſomewhat ſtalked, ſuperior, roundiſh, furrowed; ſtyle thread-ſhaped, the length and poſition of the ſtamens; ſtigma globoſe, aſcending. *Peric.* none, except the permanent hardened baſe of the corolla. *Seed* ſolitary, ovate, with five angles, ſtanding upon the dilated, ſpreading, permanent calyx.

Eſſ. Ch. Calyx five-cleft, bell-ſhaped. Corolla funnel-ſhaped. Seed ſolitary, coated, ſtanding on the ſpreading permanent calyx.

Obſ. This genus is ſeparated from *Mirabilis*, on account of its ſhort tube, lobed limb, three inſtead of five ſtamens, and calyx much dilated after flowering. The plants which compoſe it have an herbaceous, branched, round *ſtem*, ſtalked, oppoſite, ſlightly undulated *leaves*, one of them ſmaller than its companion. The herbage is moſtly viſcid and downy, and of a diſagreeable odour. The *ſtamens* are ſaid occaſionally to vary to four.

1. O. *viſcoſus*. Viſcid Umbrella-wort. Curt. Mag. t. 434. (Mirabilis viſcoſa; Cavan. Ic. v. 1. 13. t. 19.)—Downy and viſcid. Leaves heart-ſhaped. Panicle racemoſe. Stamens longer than the corolla. Native of Peru, from whence it was ſent, about twenty-five years ago, to the royal garden at Madrid, and thence communicated to various other collections. *Root* perennial, but uſually treated as annual, like the Marvels of Peru. Whole plant covered with jointed, glandular, viſcid hairs. *Stem* two feet, or much more, in height, erect, with oppoſite ſpreading branches. *Leaves* wavy, bluntly pointed, thickiſh, but ſoft and pliant, like thoſe of *Mirabilis longiflora*. *Panicle* branched, viſcid, many-flowered, its branches beſet with whorls and ſhort cluſters of ſmall purpliſh *flowers*, the lobes of whoſe *corolla* are inverſely heart-ſhaped, and much ſhorter than the *ſtamens* and *ſtyle*. *Calyx* of the fruit pendulous, membranous, pallid, reticulated with veins. *Seed* leſs than a grain of wheat, with five tuberculated angles, dropping out of the calyx when ripe.

2. O. *glabrifolius*. Smooth-leaved Umbrella-wort. Vahl. n. 2. (Calyxhymenia glabrifolia; Orteg. Decad. 5. t. 1. Mirabilis corymboſa; Cavan. Ic. v. 4. 55. t. 379.)—Leaves heart-ſhaped, glaucous, ſmooth. Panicle corymboſe. Flowers in terminal tufts. Stamens ſhorter than the corolla. Native of Peru and New Spain. Cultivated at Madrid. Ortega deſcribes this as a glaucous plant, with the acrid flavour of a *Sedum*; glandular and villous when young, but nearly ſmooth when full-grown. *Leaves* acute, entire, rough with reverſed hairs at the edges. *Panicle* hairy, forked, corymboſe. *Flowers* ſmall, purple, in tufts at the top of each branch of the panicle. *Calyx* tipped with red.

3. O. *ovatus*. Ovate Umbrella-wort. Vahl. n. 3. (Calyxhymenia ovata; Fl. Peruv. v. 1. 45. t. 75. f. *b. Vahl.*)—Hairy and viſcid. Leaves ovate. Flower-ſtalks terminal, forked. Stamens nearly as long as the corolla. Stem erect. —Native of elevated ſpots in Peru.—*Stem* three feet high. *Plant* clothed with jointed, glandular, viſcid hairs. *Leaves* thick and veiny, acute, entire, rough-edged. *Panicle* forked, with ſolitary ſingle-flowered ſtalks. *Corolla* red, twice as large as the *calyx*, till the latter becomes dilated and membranous as the fruit advances. This is known only from the *Flora Peruviana*, as well as the two next.

4. O. *proſtratus*. Proſtrate Umbrella-wort. Vahl. n. 4. (Calyxhymenia proſtrata; Fl. Peruv. v. 1. 46. t. 75. f. *c. Vahl.*)—Leaves ovate or heart-ſhaped, downy. Flowers axillary and terminal, ſomewhat corymboſe. Stem proſtrate. —Native of hills in Peru.—*Stem* three feet long, ſtriated, ſlightly downy; branches alternate, forked in the upper part. *Leaves* ſlightly crenate, wavy, veiny. *Flower-ſtalks* from the forks of the branches, as well as terminal, or axillary, ſhort, glandular, bearing from three to eight *flowers* on little partial

partial ſtalks. Segments of the *calyx* ovate. *Corolla* purple, thrice as long, plaited. *Vahl.*

5. O. *expanſus.* Spreading Umbrella-wort. Vahl. n. 5. (Calyxhymenia expanſa; Fl. Peruv. v. 1. 45. t. 75. f. *a. Vahl.*)—Leaves ovate, ſmooth. Flower-ſtalks terminal, forked. Stamens the length of the corolla. Stem erect.—Found on very dry hills in Lima.—*Stem* ſix feet high, ſtriated. *Leaves* diſtant, obſcurely crenate, rather wavy, acute, veiny; the floral ones nearly ſeſſile. *Flower-ſtalks* terminal, forked in a corymboſe manner, bearing from ſix to eleven flowers, on unequal partial ſtalks, which are but ſlightly viſcid. *Calyx* downy and glutinous. *Corolla* purple, ſomewhat bell-ſhaped. *Seed* obovate, rough *Vahl.*

6. O. *aggregatus.* Three-flowered Umbrella-wort. Vahl. n. 6. (Calyxhymenia aggregata; Orteg. Decad. 81. t. 11. Mirabilis aggregata; Cavan. Ic. v. 5. 22. t. 437.)—Leaves lanceolate. Flower-ſtalks axillary, ſolitary. Calyx with about three flowers.—Native of New Spain. It flowered in 1798 at Madrid.—*Stem* a foot high or more, branched from the very baſe, ſtriated, leafy. *Leaves* nearly ſeſſile, about two inches long, oppoſite, lanceolate, thickiſh, wavy, ſmooth, rough edged. *Flower-ſtalks* axillary, ſometimes from the forks of the branches, ſolitary, ſhort, drooping when in fruit. *Calyx* bell-ſhaped, with unequal ovate ſegments, containing uſually three *flowers*, rarely two or four, which are ſeſſile, without any other perianth. *Corolla* reddiſh. *Stamens* the length of the *corolla*. The *calyx* is enlarged when in fruit, as in the other ſpecies. *Seeds* ſeldom more than two perfected, large, villous, at firſt enveloped by the *calyx*, which at length becomes expanded.

OXYACANTHA. See BERBERIS.

OXYBLATTA, among the *Ancients*, is uſed to denote a bright and gloſſy kind of purple colour.

OXYCANI, in *Ancient Geography*, a people of India, who occupied the territory now called Hajycan or Hajykan, a circar or diviſion of Sindy.

OXYCEDRUS, in *Botany*. See JUNIPERUS.

OXYCOCCUS, from οξυς, *acid*, and κοκκος, *a berry*; the Cranberry. See VACCINIUM; from which ſome have disjoined this plant, becauſe the *corolla* is very deeply divided, even to the very baſe; ſo that Roth, who has called this ſuppoſed new genus *Schollera*, deſcribes it as tetrapetalous. He alſo takes for additional characters the tubular points of the anthers, and the approximation of their filaments. The laſt is ſurely of little avail, and the former occurs in *Vaccinium ſtamineum*, whoſe *corolla*, nevertheleſs, is perfectly monopetalous; as well as probably in many other ſpecies; theſe organs being variouſly conſtructed in that genus, like thoſe of its relation *Erica*. Linnæus had long ago conſidered this matter, and he aſſerts in *Flo. Lapp.* ed. 2. 118, that "the great Tournefort was wonderfully deceived in conſidering the Cranberry as polypetalous; for if the flower be examined at its firſt opening, it will be found monopetalous, ſlightly four-cleft at the margin, though it ſubſequently ſplits, and falls off in four parts." Did Dr. Roth eſtabliſh his genus without conſidering this paſſage? He does not cite the work. See *Roth Germ.* v. 1. 170. v. 2. 442. We have only to add, that if this genus were eſtabliſhed, *Oxycoccus* muſt remain with it, as an unexceptionable name.

OXYCRATE, OXYCRATUM, οξυκρατον, formed of οξυς, *ſharp*, *ſour*, and κεραννυμι, *I mix*, in *Pharmacy*, &c. a mixture of water and vinegar.

The uſual proportion is one ſpoonful of vinegar to five or ſix of water.

Oxycrate is proper to aſſuage, cool, and refreſh. They make fomentations of oxycrate, clyſters of oxycrate, &c.

OXYCROCEUM, formed from οξυς, *ſharp*, *ſour*, and κροκος, *ſaffron*, a preparation uſed in plaſters for fractures, and to form calluſes; compoſed chiefly of ſaffron, with gums diſſolved in vinegar.

OXYD, or OXIDE, in *Chemiſtry*, a term that may be properly applied to any ſubſtances chemically combined with oxygen; but it is reſtricted to thoſe that have not acquired acid properties by the combination. This term is chiefly uſed to expreſs thoſe modifications of metallic bodies formerly termed "calces." See CALCINATION.

For the oxyds of antimony, arſenic, iron, lead, mercury, &c. ſee the ſeveral articles.

OXYDRACÆ, in *Ancient Geography*, a people of India, who inhabited the diſtrict now called Outch, near the confluence of the Aceſines (Chunaub) with the Indus.

OXYGALA, οξυγαλα, formed from οξυς, *ſharp*, *ſour*, and γαλα, *milk*, ſour milk.

The Turks uſe this as a popular drink, and call it *igur*. Vigenere ſays, they drink ſour milk diluted with water; which is found to cool and nouriſh better than the milk alone.

OXYGARUM, a word uſed by the ancients to expreſs a mixture of vinegar and garum, which is a pickle for preſerving fiſh, or a ſimple mixture of ſea-ſalt and water.

OXYGEN GAS, French nomenclature; *Dephlogiſticated air* of Dr. Prieſtley; *Empyreal and vital air* of others.

This important element is very generally diffuſed throughout nature. It exiſts in the atmoſphere, and in water; it is often found in combination with metallic baſes, and it conſtitutes one of the ultimate principles of almoſt all animal and vegetable matter. It is eſſential to the reſpiration of animals, and is frequently abſorbed by plants, contributing to the healthy performance of ſome of their moſt intricate functions.

Oxygen gas was diſcovered by Dr. Prieſtley in the month of Auguſt 1774. He obtained it by heating *red precipitate* in a ſmall glaſs retort connected with the hydro-pneumatic apparatus. This compound of quickſilver and oxygen is decompoſed at a low red heat, the quickſilver diſtils over, and the oxygen aſſumes the gaſeous form. In conſequence of properties preſently to be noticed, Dr. Prieſtley termed it *dephlogiſticated air*. While theſe experiments were carrying on in England, Scheele, in Sweden, was engaged in inveſtigating the nature of the ores of manganeſe, and in the courſe of the year 1775, he procured oxygen gas without any previous knowledge of Prieſtley's diſcovery.

Lavoiſier, in his "Elements of Chemiſtry," Engliſh tranſlation, p. 36. v. 1. ſays, "this ſpecies of air" (meaning oxygen) "was diſcovered about the ſame time by Mr. Prieſtley, Mr. Scheele, and myſelf." In a pamphlet publiſhed in 1800 by Dr. Prieſtley, after his return to America, entitled "The Doctrine of Phlogiſton eſtabliſhed, and that of the Compoſition of Water refuted," there is the following remark upon the ſubject of this brilliant and important diſcovery, which we tranſcribe without comment. "The caſe was this. Having made the diſcovery ſome time before I was in Paris in the year 1774, I mentioned it at the table of Mr. Lavoiſier, when moſt of the philoſophical people in the city were preſent, ſaying, that it was a kind of air in which a candle burned much better than in common air, but I had not then given it any name. At this all the company, and Mr. and Madame Lavoiſier, as much as any, expreſſed great ſurpriſe. I told them I had gotten it from *precipitate per ſe*, and alſo from *red lead*. Speaking French very imperfectly, and being little acquainted with the terms of chemiſtry, I ſaid *plomb rouge*, which was not underſtood till Mr. Macquer ſaid, I muſt mean *minium*. Mr. Scheele's diſcovery

diſcovery was certainly independent of mine, though I believe not made quite ſo early."

Oxygen gas may be procured from a variety of ſources, but two only are generally had recourſe to. For delicate inveſtigations, where it is required to be abſolutely pure, it may be obtained by heating the compound termed *oxymuriate of potaſh*. One hundred grains of this ſalt, at a low red heat, yield from 100 to 110 cubical inches of oxygen in a ſtate of great purity. For all the common purpoſes of experiment, however, it may be procured by heating to redneſs in an earthen or iron retort, the ſubſtance called *black oxide of manganeſe*, of which one pound in fine powder affords about 1400 cubic inches of tolerably pure oxygen gas. This oxyd of manganeſe is a very abundant article; it ſhould be purchaſed in lumps, for when powdered, it is apt to be mixed with extraneous matter, which interferes with the production of pure oxygen; indeed, the firſt portions which paſs off are rarely pure, and ſhould be collected in a ſmall tube, and teſted by the introduction of an inflamed taper; if this burns with greatly increaſed brilliancy, the oxygen may be regarded as ſufficiently free from impurities. Nitrate of potaſh or ſaltpetre, minium, or red oxyd of lead, and ſeveral other ſubſtances containing oxygen, afford it when heated to redneſs.

Oxygen may alſo be obtained by mixing the oxyd of manganeſe in a glaſs retort, with its weight of ſulphuric acid (oil of vitriol); the heat of a patent lamp will then be ſufficient to cauſe a copious evolution of the gas; there are, however, ſome black oxyds of manganeſe which evolve an abundance of the gas at a red heat, but yield it ſparingly when acted upon by the acid; and *vice verſâ*. The cauſe of this has not been explained.

In all the above experiments, the manganeſe only loſes a *portion* of its oxygen, the remainder being retained in combination with the metal by a very powerful attraction. The oxyd, after expoſure to a red heat till it gives off no more gas, acquires a brown colour, and if it be moiſtened and expoſed to the atmoſphere, it is ſuſceptible of abſorbing oxygen, and may thus be again uſed as a ſource of the gas; it may alſo be uſed to procure *chlorine*. See OXYMURIATIC *Acid*.

The only foreign matter contained in the gas, derived from oxymuriate of potaſh, is a little aqueous vapour, from which it may be freed by expoſure to cauſtic potaſh, or to fuſed muriate of lime; one or other of theſe ſubſtances may be introduced into the gas over quickſilver, and retained there until the whole of the moiſture is abſorbed, which is known by the freſh pieces of the ſubſtance remaining dry; the gas is then decanted into another veſſel, and may be regarded as perfectly pure. In this ſtate it exhibits the following characteriſtic properties.

It is permanently elaſtic at all known temperatures; colourleſs, tranſparent, and without ſmell and taſte.

It is reſpirable, and may be breathed for ſome time without inconvenience.

Its ſpecific gravity, compared to atmoſpheric air, is as 1003 to 1000; to hydrogen as 15 to 1. At a mean temperature and preſſure, 100 cubic inches weigh 34 grains.

When an inflamed taper is immerſed in oxygen gas, it burns with greatly increaſed ſplendour, and is much more rapidly conſumed than in atmoſpheric air; and when the wick is merely glowing, it is inſtantly rekindled with a ſlight exploſion. When ſteel or iron wire, with a bit of inflamed wood attached to it, is introduced into the gas, the metal burns with great brilliancy, and throws off white hot ſparks and globules, conſiſting of the protoxyd of iron. When ſulphur, phoſphorus, or charcoal, are burned in oxygen, the combuſtion is intenſely vivid, and *acids* are formed by the union of the two bodies. This circumſtance induced the French chemiſts to introduce the term *oxygen* (from οξυς), and they regarded it as a neceſſary component part of all acids; but the extenſion of experiment has ſhewn that this is far from true; and in many inſtances the abſorption of oxygen gives riſe to alkaline and earthy products, ſo that the term is very objectionable.

Conceiving that ſo powerful a ſupporter of combuſtion as this gas muſt in itſelf contain little or no phlogiſton, Dr. Prieſtley termed it *dephlogiſticated air*. See COMBUSTION.

The French theoriſts conſidered oxygen as neceſſarily preſent in all caſes of combuſtion, under which article will be found a detailed account of the ſubject; but experiment does not ſupport the concluſion, and there are abundant inſtances of combuſtion, not merely where no oxygen gas is preſent, but where ſolids and fluids act upon each other, independent of the abſorption or decompoſition of any aeriform matter. See OXYMURIATIC *Gas*.

Oxygen gas is very ſparingly abſorbed by water; when that fluid has been deprived, by boiling, of the atmoſpheric air which it contains, it takes up $\frac{1}{27}$th its bulk of oxygen, at the temperature of 60°.

If the number repreſenting oxygen be deduced from the analyſis of water, (ſee HYDROGEN and WATER,) it will be 7.5, for that fluid is compoſed of one volume of hydrogen and half a volume of oxygen, and the weights of *equal* volumes of theſe gaſes are to each other as 1 to 15. Or if, to obviate the uſe of fractional parts, we regard water as compoſed of *two* proportions of hydrogen, and *one* of oxygen, the ſymbol of the latter gas will be 15; and water compoſed of 15 oxygen + 2 hydrogen, will be repreſented by the number 17, inſtead of 8.5, as in the former inſtance. B.

OXYGENATION, in *Agriculture*, the act of uniting oxygen with different ſubſtances; when it is combined with earthy materials, ſuch as mould, clay, &c. they are found from experience to be more proper for the nutrition and ſupport of different ſorts of vegetables as crops.

OXYGLUCA, a word uſed by the ancients to expreſs a liquor made of a mixture of honey, water, and vinegar. The common way of making it was by macerating the combs, after the honey was preſſed out, in water; and then adding a ſmall portion of vinegar, to give it a tartneſs. It was ſometimes made without the addition of the acid, and made a weaker ſort of mead, uſed as a common drink in hot weather. Galen ſays it was the ſame with the *apomeli*.

OXYGONIUS, OXYGONOUS, formed of οξυ, and γωνη, *angle*, in *Geometry*, *acute-angled*; a figure conſiſting wholly of acute angles, or angles leſs than ninety degrees.

The word is chiefly applied to triangles, where the three angles are all acute, or leſs than ninety degrees each.

OXYLIPES, a word uſed by ſome authors as a name for bread, which has a mixture of vinegar in it; intended ſometimes for eating, ſometimes for medicinal uſes.

OXYLOBIUM, in *Botany*, from οξυς, *ſharp*, and λοβος, *a pod* or *legume*, alluding to the ſharp point or beak of that part. Andr. Repoſ. 492. Brown in Ait. Hort. Kew. v. 3. 9. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, ſomewhat two-lipped, in five deep ſegments, without appendages; the three lower ones rather moſt deeply ſeparated. *Cor.* papilionaceous, of five petals; ſtandard roundiſh, broad, with a ſhort claw; wings obovate, a little ſhorter than the ſtandard, oblique at the baſe, with ſhort, linear claws; keel compreſſed, as long

as the wings, of two heart-ſhaped petals cohering at their ſummits, with two ſhort, linear, diſtinct claws. *Stam.* Filaments ten, awl-ſhaped, aſcending, all encloſed in the keel; anthers roundiſh. *Piſt.* Germen ovate; ſtyle awl-ſhaped, aſcending, permanent and finally hardened; ſtigma ſimple. *Peric.* Legume ovate, turgid, acute, of one cell. *Seeds* ſeveral, roundiſh-kidney-ſhaped, inſerted into the margin of each valve at the dorſal future.

Eſſ. Ch. Calyx deeply five-cleft, ſomewhat two-lipped. Corolla papilionaceous; keel compreſſed, nearly as long as the ſpreading ſtandard. Style aſcending. Stigma ſimple. Legume ovate, inflated, pointed, of one cell with ſeveral ſeeds.

1. O. *arboreſcens.* Tall Oxylobium. Ait. n. 1.—Leaves linear-lanceolate. Bracteas permanent, at the top of the flower-ſtalk. Corymbs denſe. Legume ſcarcely longer than the calyx.—Found by Mr. Brown, in Van Diemen's land; brought to Kew garden in 1805, where it flowers from April to June, and is kept in the greenhouſe. The *ſtem* is ſhrubby or arboreſcent. Nothing further is, as yet, recorded of this ſpecies, nor have we ever ſeen a ſpecimen.

2. O. *ellipticum* Oval-leaved Oxylobium. Ait. n. 2. (Gompholobium ellipticum; Labillard. Nov. Holl. v. 1. 107. t. 135. Calliſtachys elliptica; Vent. Malmaiſ. 115, b. Calliſtachya elliptica; Sm. Tr. of Linn. Soc. v. 9. 266.)—Leaves elliptic-oblong. Bracteas below the top of the flower-ſtalk, deciduous. Corymbs denſe. Legumes twice the length of the calyx.—Diſcovered firſt by the late Mr. David Nelſon, in Van Diemen's land, from whence it was brought to Kew by Mr. Brown, in 1805. It is kept in the greenhouſe, and flowers moſt part of the ſummer. Ventenat, having never ſeen the fructification, referred the plant by its habit to his *Calliſtachys*, but proves to be miſtaken. We know it only by Mr. Brown's ſpecific character; and the plate and deſcription of Labillardiere, according to whom the *ſtem* is ſhrubby, nine feet high, with upright ſilky branches that are ſometimes whorled. *Leaves* imperfectly whorled, near an inch long, on ſhort ſtalks, elliptical, entire, revolute, ſilky beneath, tipped with a ſmall point. *Stipulas* none. *Flowers* numerous, in denſe, ſhort, ſilky corymbs. We preſume the *corolla* is yellow, but Labillardiere, having deſcribed from his dried ſpecimens only, generally omits that particular. The *legume* is clothed with denſe, twiſted, yellowiſh hairs, which are very ſenſible hygrometers.

3. O. *cordifolium.* Heart-leaved Oxylobium. Andr. Repoſ. t. 492. Curt. Mag. t. 1544. Ait. n. 3.—Leaves ovate, ſomewhat heart-ſhaped, looſely hairy. Umbels terminal, ſeſſile, of few flowers. Diſcovered in New South Wales, by the right honourable ſir Joſeph Banks, in the courſe of his celebrated voyage. Seeds were imported by Mr. Loddige, who raiſed plants from them about 1804 or 1807. This ſhrub is kept in the greenhouſe, and bloſſoms throughout the ſummer, producing plenty of ſeeds, by which, or by cuttings, it is readily increaſed. It is of humble growth, with numerous, partly whorled, round, hairy, purpliſh, leafy *branches*. *Leaves* three in a whorl, rarely oppoſite or ſolitary, nearly ſeſſile, ſcarcely half an inch long, broad-ovate or ſomewhat heart-ſhaped, acute, revolute, entire; paler beneath; very rough at the edges, and hairy all over in ſome degree. *Flowers* of a rich deep orange, verging towards ſcarlet, from three to ſix in each cloſe terminal *umbel*. *Standard* marked with a yellow ſpot, and a deep red curved line, at its baſe. *Seeds* about five, black, clouded.

OXYMEL, οξυμελι, formed from οξυς, *ſour*, and μελι, *mel*, *honey*, in *Pharmacy*, a mixture of honey and vinegar boiled to the conſiſtence of a ſyrup.

Oxymel, *Simple*, is compoſed of two pounds of clarified honey, and a pint (lb.) of acetic acid (diſtilled vinegar), boiled in a glaſs veſſel by a gentle heat into the conſiſtence of a ſyrup.

Simple oxymel in doſes of f℥j, or more, diſſolved in barley water, forms a pleaſant and cooling beverage in fevers and inflammatory affections. It is often added to gargles in cynanche tonſillaris, and is a common article of other remedies in catarrhal complaints. The Dublin college orders it to be prepared with unclarified honey, ſkimming it during the boiling; but the London directions are to be preferred.

Oxymel *Colchicum of Storck.* (See Colchicum.) It is obſervable, that the active matter of the colchicum is apt to be injured by the boiling; and hence this preparation is very uncertain, with regard to its ſtrength. It is given in humoral aſthmas, and in dropſies. The doſe is f℥j, gradually increaſed, to f℥j, given in a cupful of gruel, twice a-day.

Oxymel *Scillæ*, oxymel of ſquills, is prepared by boiling three pounds of clarified honey in two pints (pounds) of vinegar of ſquill in a glaſs veſſel, over a gentle fire, to a proper conſiſtence. This is principally employed as an expectorant, and as ſuch, is very uſeful in humoral aſthma, and chronic coughs, in doſes from f℥ſs to f℥ij. It is generally given in ſome aromatic diſtilled water, to prevent the nauſea which it is apt to induce; in large doſes it is given to excite vomiting, and at the ſame time to clear the cheſt, in hooping-cough.

Oxymel *Æruginis*, oxymel of verdigris, conſiſts, according to the Dublin college, of the following ingredients, *viz.* prepared verdigris, one ounce; wine vinegar, ſeven fluid ounces; and clarified honey, fourteen ounces. Diſſolve the verdigris in the vinegar, and ſtrain it through a linen cloth; add the honey, and boil the mixture to a proper thickneſs. This preparation is detergent and eſcharotic. In the above ſtate it is uſed for taking down fungous fleſh; and conſiderably diluted, it is an uſeful ſtimulant to foul ulcers, which it clears, and excites to a more healthy action. It has been employed as a gargle in venereal ulcerations of the mouth and fauces; but, Mr. Thomſon ſays, we cannot recommend it.

OXYMORON, or *ſeeming contradiction*, in *Rhetoric*, is a ſpecies of antitheſis, when the parts of a ſentence diſagree in ſound, but are conſiſtent in ſenſe. Thus Ovid, lib. viii. ver. 47, ſays of Althea, *impietate pia eſt.*

OXYMURIATIC *Acid Gas*, French nomenclature; *Dephlogiſticated muriatic acid gas* of Scheele; *Chlorine*, or *Chloric gas*, of ſir H. Davy.

The ſubſtance which has received theſe various names was diſcovered in the year 1774, by the illuſtrious Scheele, and regarding it as muriatic acid deprived of hydrogen, he gave it the name of dephlogiſticated marine acid.

In the year 1785, Berthollet publiſhed a ſeries of experiments upon the ſame ſubject, from the reſults of which he drew inferences very oppoſite to thoſe of Scheele; for inſtead of regarding it with his predeceſſor as an elementary body, and as the baſis of muriatic acid, he was induced to conſider the muriatic acid as a ſimple form of matter, and to conclude that the dephlogiſticated muriatic acid gas of Scheele conſiſted of muriatic acid in combination with oxygen, whence the term oxymuriatic acid gas.

Berthollet's experiments appeared ſo ſatisfactory, and his reſults ſo concluſive, as to lead to the general adoption of his opinions by the chemiſts of Europe; but in the year 1810, ſir Humphrey Davy preſented the Royal Society with a paper, entitled "Reſearches on the Oxymuriatic Acid, its Nature and Combinations, &c." (ſee Phil. Tranſ. 1810, page 231.) in which, after quoting the opinions of the authors alluded to, and of other experimentaliſts, he details a ſeries

a ſeries of inveſtigations which demonſtrate the inaccuracy of Berthollet's views, and in a great meaſure re-eſtabliſh the correctneſs of thoſe of Scheele: theſe will be noticed in due order, and the reaſons ſtated which induced ſir H. Davy to give to the ſubject of this article the name of *Chlorine*.

Many objections have been ſtarted to this revival of the Scheelian doctrine by the advocates of the French ſchool, but they are hypothetical not experimental, and to meddle with ephemeral controverſialiſts is below the dignity of a Cyclopædia, which aims at the exalted taſk of recording the truths of ſcience, and of tranſmitting to poſterity the ſucceſsful inſtruments of its progreſs.

Chlorine may readily be procured by heating in a glaſs retort a mixture of equal weights of the black oxyd of manganeſe and common muriatic acid, (ſpirit of ſalt.) The gas is ſoon liberated, and may be conveniently collected over warm water. In this proceſs the oxygen of the oxyd of manganeſe unites to the hydrogen of the muriatic acid, while the chlorine, the other element of the muriatic acid, is diſengaged in the pure and gaſeous form. The correctneſs of this view may be demonſtrated by a more refined experiment. Introduce into a glaſs retort, ſupplied with a ſtopcock, a ſmall quantity of black oxyd of manganeſe, exhauſt the retort by means of an air-pump, and fill it with pure muriatic acid gas. If a gentle heat be now applied, a decompoſition of the gas, and a partial decompoſition of the oxyd of manganeſe, will be effected; the hydrogen of the former, combining with a portion of the oxygen of the latter, produces water, which collects in drops in the cool part of the retort, and a quantity of chlorine, equal to one-half of the volume of muriatic acid decompoſed, is liberated. By ſuch decompoſition of the muriatic acid gas, the proportion of its elements may be accurately aſcertained. Thus, if the number 1 be employed to repreſent hydrogen, 33.5 will be the ſymbol for chlorine, and 34.5 (*i.e.* 1 + 33.5) for the muriatic acid, theſe numbers repreſenting the reſpective elements *by weight*. The ſynthetic demonſtration conſiſts in detonating, by the electric ſpark, one volume of chlorine with one of hydrogen; they combine without change of bulk, and two volumes of muriatic acid gas are produced.

Another mode of procuring chlorine conſiſts in diſtilling a mixture of about eight parts of decrepitated common ſalt, three parts of black oxyd of manganeſe, and five parts of ſulphuric acid diluted with half its weight of water. In this caſe the ſulphuric acid, which conſiſts of ſulphur, oxygen, and water, decompoſes the marine ſalt, conſiſting of ſodium and chlorine: the ſodium is oxydized at the expence of the water of the acid, the hydrogen of which unites to the chlorine of the ſalt, and produces muriatic acid, which is in its turn decompoſed by the oxyd of manganeſe as above deſcribed.

Although chlorine can only be conveniently collected in the hydro-pneumatic apparatus, yet as it is ſlowly abſorbed by water it cannot be retained in contact with that fluid, and ſhould therefore be preſerved in bottles with ground glaſs ſtoppers

Chlorine has the following properties:

Its colour is, as its name imports, (from χλωρος) greeniſh-yellow.

It has a peculiar ſuffocating odour, and when reſpired is inſtantly fatal: even when largely diluted with atmoſpheric air it produces highly deleterious effects, ſuch as cough, catarrhal affection, and great irritation of the lungs. Theſe are circumſtances which render much caution neceſſary in collecting and examining the gas.

One hundred cubic inches of chlorine, at a mean temperature and preſſure, weigh 76 grains. At the temperature of 60° Fahrenheit, one volume of water diſſolves about two of chlorine: the ſolution has the odour and colour of the gas: its taſte is nauſeous and aſtringent. By means of Wolfe's apparatus water may be conveniently ſaturated with this gas: the contents of the firſt bottle ſhould be rejected as containing a portion of muriatic acid, which paſſes over during the diſtillation.

When a burning wax taper is plunged into a bottle of chlorine, the brilliancy of its flame is greatly impaired; it exhibits a dull red light, and throws off a large quantity of charcoal.

The attraction of chlorine for the metals is in moſt inſtances extremely energetic: when copper leaf, or antimony, or arſenic in powder, are thrown into the gas, they immediately enter into vivid combuſtion and form binary compounds, and if the oxyds of theſe and many other metals be heated in chlorine, oxygen is expelled, and ſimilar compounds of the metal and chlorine reſult.

Upon the French theory of combuſtion, oxygen is abſolutely neceſſary to the phenomena (ſee Combustion), but here are inſtances of brilliant inflammation without the preſence of that body. Other caſes might be adduced, ſuch as the combuſtion which enſues when copper filings and ſulphur are heated together in an exhauſted veſſel; or when potaſſium and arſenic are made to combine under ſimilar circumſtances.

Combuſtion, therefore, is to be regarded as the general reſult of the exertion of powerful chemical attraction, and not as dependent upon any peculiar ſubſtance, or as reſulting from the decompoſition of any diſtinct form of matter.

When ſulphur is heated in chlorine the two bodies readily combine, and form a peculiar compound, which was firſt deſcribed by Dr. Thomſon of Edinburgh. See Sulphur.

When phoſphorus is introduced into chlorine, it ſpontaneouſly ignites and burns with a pale yellowiſh flame, producing a white volatile ſubſtance, compoſed of two proportions of chlorine and one of phoſphorus. There is alſo a compound of phoſphorus and chlorine compoſed of one proportion of each of its elements, and conſequently containing only half as much chlorine as the former. It may be obtained by diſtilling in a cloſe veſſel a mixture of corroſive ſublimate and phoſphorus. It is a limpid liquor, which emits acid fumes when expoſed to air. See Phosphorus.

For our knowledge of theſe compounds, and of their ſingular properties, we are indebted to the experimental induſtry of ſir H. Davy.

Charcoal and chlorine have not hitherto been combined. If a piece of charcoal be ignited to whiteneſs by means of the Voltaic battery, in a veſſel of chlorine, there is no mutual action: the colour of the gas remains unimpaired, and the charcoal unaltered: no carbonic acid is formed.

This circumſtance firſt led ſir H. Davy to doubt the accuracy of Berthollet's inveſtigation, and to undertake the ſeries of inquiries concerning the nature and properties of chlorine, which have been alluded to. Chlorine, or oxy-muriatic acid gas of the French nomenclature, was ſuppoſed to contain oxygen in a very looſe ſtate of combination, an idea ſufficiently diſproved by the experiment juſt related; and whenever oxygen appears to be procured, it is derived either from water or ſome other ſource. Neither intenſe ignition, nor exceſſive cold, produce any change in chlorine. It has uſually been ſtated to ſolidify at the temperature of freezing water; but if the gas be carefully dried, no ſolid matter is depoſited. The concentrated aqueous ſolution freezes at 40°.

When no moiſture is preſent, chlorine effects no change upon vegetable colours; but if the gas has not been very carefully dried by expoſure to muriate of lime, or if the coloured

coloured ſubſtance introduced into it is the leaſt damp, it fades, and acquires a yellow tint, and almoſt all coloured ſolutions ſuffer the ſame change. This remarkable effect, which has generally been regarded as ariſing from the communication of oxygen to the colouring matter by the chlorine, ſeems to depend upon more intricate changes; it is perhaps connected with the production of muriatic acid and of oxygen, in conſequence of the action of chlorine upon water.

The uſes of chlorine in the art of *bleaching*, and the peculiar modes of its application, have already been deſcribed, (ſee BLEACHING.) Mr. Watt of Birmingham, and Mr. Henry of Manchester, are intitled to the merit of having firſt introduced this new method of bleaching into England. It originated with Berthollet.

In the year 1811, ſir H. Davy diſcovered a gaſeous compound of chlorine and oxygen; its colour is more intenſe than that of chlorine, a circumſtance which induced him to call it euchlorine, from ευ and χλωρος. To obtain this gas, ſome oxymuriate of potaſh ſhould be introduced into a very ſmall glaſs retort, and a mixture of equal parts of muriatic acid and water poured upon it. Twenty grains of the cryſtallized oxymuriate to half an ounce of the dilute acid, are good proportions. On the cautious application of a very gentle heat, the euchlorine paſſes over, and muſt be collected in the mercurio-pneumatic apparatus.

The ſmell of this gas differs from, and is much leſs diſagreeable than, that of chlorine. It is unreſpirable. Water takes up eight times its volume of euchlorine, and forms a lemon yellow ſolution. Its weight, compared with that of hydrogen, is as 33 to 1. One hundred cubic inches weigh 75 grains.

When euchlorine is heated to a temperature between 100° and 150° it expands with exploſion, and is reſolved into its conſtituent parts, *viz.* two volumes of chlorine and one of oxygen. It exerts no action upon thoſe metals which inflame in, and energetically combine with, chlorine. If copper leaf, for inſtance, be introduced into pure euchlorine, it is not even tarniſhed, but if heat be applied ſo as to decompoſe the gas, the metal is inſtantly ignited, and burns as in a mixture of two parts of chlorine and one of oxygen. Phoſphorus, an inflamed taper, and ſulphur in a ſtate of combuſtion, immediately decompoſe euchlorine, and exhibit the ſame phenomena as when burned in an artificial mixture of its elementary gaſes.

The above mentioned experiments and others, ſhew that euchlorine is compoſed of one proportion of oxygen = 7.5, and one of chlorine = 33.5, and conſequently its repreſentative ſymbol is 41.

In this article the term chlorine has been preferred to that of oxymuriatic acid, not merely on account of its brevity and propriety, but as founded upon an obvious and unalterable character of the body it repreſents, namely, its colour; and a change of nomenclature became abſolutely neceſſary to the ſyſtematic writer; for it would in him be abſurd to call a body *oxymuriatic acid*, which exhibits no acid characters, and in which neither oxygen nor muriatic acid have hitherto been demonſtrated to exiſt. B.

The editor of the Cyclopædia is fully apprized of the importance of giving accurate details of the origin and progreſs of every art and ſcience that are comprehended within the limits of the multifarious work in which he is engaged; and of doing ample juſtice to thoſe ingenious men, whoſe only recompence for valuable diſcoveries is, in moſt caſes, the reputation which they thus acquire. It is, therefore, without heſitation, that he complies with the wiſhes of a friend, no leſs reſpected and eſteemed for his eminent attainments in ſcience, than for his general character, by ſupplying the defects and correcting the errors which he has pointed out to him in the article BLEACHING. He much regrets that the name of Mr. Henry, of Manchester, whom he has long known and honoured, and the part which he took in the improvement of this branch of our manufactures, ſhould not have been noticed by the ingenious compiler of that article. Avoiding every thing that may be likely to produce perſonal animoſity and altercation, the editor thinks it moſt adviſable to content himſelf with giving a fair and full ſtatement of Mr. Henry's claims, and this ſhall be done as nearly as poſſible in the words of his correſpondent, Dr. W. Henry. He begins with alleging, that the writer of the article abovementioned, "in aſſigning to different perſons their ſhares of merit, in the introduction of the new mode of bleaching by oxymuriatic acid and its compounds, has made a diſtribution, which is very far from being fair or equitable." "Of the part," he ſays, "taken by Mr. Watt of Birmingham, in the application of this moſt important diſcovery, much too little is ſaid; and of my father's ſhare in the improvement, which was both an early, an active, and an expenſive one, not the ſmalleſt notice is taken throughout the whole article; though it was a matter of too much notoriety to have eſcaped the knowledge of any perſon in this neighbourhood."—"The fact is, that next to Mr. Watt, who had very early a perſonal communication with Mr. Berthollet on the ſubject, (ſee Annales de Chimie, ii. 160.), and who appears to have made the firſt experiments that were attempted in this country, my father was at leaſt equally early with any other perſon."—"It happens, fortunately for the eſtabliſhment of the claim of Mr. Watt and my father, that I am in poſſeſſion of a ſeries of letters from the former to the latter, communicating unreſervedly, in return for ſimilar information, what he was doing with a view to the practical application of Berthollet's diſcovery. In one of theſe letters (Feb. 23. 1788) Mr. Watt ſtates, that at that very time 1500 yards of linen "were bleaching" by the new proceſs under his directions. In the ſame letter he alludes to "an advertiſement calling a meeting of the Mancheſter manufacturers and merchants to conſider of a petition preſented by certain foreigners —— to parliament, concerning a certain liquor made from native ſalt; which whitens linen, &c. in a ſhorter time, and without many inconveniences and loſſes, to which the old method was liable."

Dr. Henry further ſtates, that the piece of calico, ſaid, in the article of BLEACHING, to have been bleached by the new proceſs in the ſpring of 1788, was bleached immediately before the meeting to which Mr. Watt alludes in the fore-cited letter, and half a piece was produced at the meeting, in order to furniſh a reaſon for reſiſting the above-mentioned application of the foreigners. But, "there is every probability," ſays Dr. H., "that before this was done, the 1500 yards bleaching under Mr. Watt's inſtructions, muſt have been finiſhed; and that, conſequently, that diſtinguiſhed philoſopher had the priority to Meſſrs. Cooper, Baker, and Taylor. But, however this may be, my father, at the ſame public meeting where Mr. Cooper ſhewed his ſpecimen, produced, not half a piece, but half a yard, of calico, bleached by the oxymuriatic acid. What was wanting in quantity, however, was made up in the quality of the work; for the ſpecimen was declared to be ſuperior to Mr. Cooper's in whiteneſs; and its ſuperiority led to an acquaintance between my father and one of the bleachers preſent, who concurred in this opinion, and to the inſtruction of this gentleman (Mr. Ridgway of Harwich) by my father in the new mode of bleaching."

Mr. Cooper, it is ſaid, eſtabliſhed a large bleaching concern,

cern, which failed; and Mr. Henry's, on a ſmaller ſcale, was relinquiſhed in conſequence of the diſhonourable conduct of a partner.

The event of the town's meeting, already mentioned, was, "that in conſequence of the facts, which were ſtated on the authority of Mr. Watt, Mr. Cooper, and my father, inſtructions were given to the members of parliament for the county to oppoſe the petition; and its prayer was accordingly refuſed." Afterwards, when application was made for a patent, Mr. Henry drew up a memorial, which was preſented to the attorney-general againſt the claim of the petitioners, and which contributed, at leaſt in a conſiderable degree, to their want of ſucceſs. This document, which is ſtill preſerved, places beyond all controverſy Mr. Henry's right to rank among the firſt improvers of the proceſs of bleaching.

It ought alſo to be mentioned that the firſt thing attempted by Mr. Henry was "an eſtabliſhment for preparing bleaching liquor, and ſelling it to conſumers. This liquor was prepared by receiving the oxymuriatic acid gas into a ſolution of cauſtic potaſh. It was ſoon found, however, that the liquor, though very good at firſt, loſt its power by keeping, in conſequence of the decompoſition of the acid, on a principle ſince explained by Mr. Chenevix, and the formation of hyper-oxymuriate and common muriate of potaſh. It was by diſappointment from this cauſe (an effete liquor having been ſent to Mr. Hoyle and others) that my father was influenced to take up the buſineſs of bleaching, in which he would probably have continued till this day, had it not been for the diſhonourable conduct of his partner."

After the preceding ſtatement, the editor thinks himſelf warranted, both in juſtice and honour, to recommend the following inſertions in the article of BLEACHING. At the cloſe of the 11th line of col. 2. p. 5. of that article, *viz.* before any conſiderable bleaching work was eſtabliſhed in France, let the following ſentence be introduced. "A very early and active ſhare was taken alſo in the introduction of the new mode of bleaching by Mr. Henry of Mancheſter and Mr. Watt of Birmingham. The latter gentleman, (who had been preſent at ſome experiments of Berthollet on the bleaching power of oxymuriatic acid,) in the month of February 1788 actually whitened 1500 yards of linen by this method. To his exertions, and to thoſe of Mr. Henry, who extended the ſcale of his operations from ſmall experiments to a regular eſtabliſhment for the purpoſe, and to the co-operation of the principal manufacturers of Mancheſter, it was owing, that ſome foreigners, who had brought with them into this country the knowledge of Berthollet's proceſs, were prevented from obtaining an excluſive and moſt injurious monopoly."

The editor alſo requeſts that the paragraph in line 27. p. 6. may be altered and read as follows: "One of the firſt of theſe ſucceſsful inſtitutions for alkali, invented by Mr. Henry of Mancheſter, and practiſed, under his inſtructions, by the bleachers of cotton hoſe at Nottingham, was," &c. &c. and let the paragraph terminate with the words "and enabled the perſons to let the goods down into the fluid."

OXYOPIA, from οξυς, *ſharp*, and οφις, *viſion*, in *Surgery*, a peculiar acuteneſs of ſight, ſometimes obſerved in fair perſons.

OXYPETALUM, in *Botany*, from οξυς, *ſharp*, and πεταλον, *a petal*, Brown in Tr. of the Wernerian Soc. v. 1 41. Claſs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocyneæ*, Juſſ. *Aſclepiadeæ*, Brown.

Eſſ. Ch. Corolla with a ſhort inflated tube; the limb in five deep ſegments, each with a ligulate appendage above. Crown of the ſtamens of five roundiſh, ſimple, fleſhy leaves. Anthers tipped with a membrane. Maſſes of pollen linear, pendulous, attached to the curvature of the proceſſes, which are ſubſequently turned upwards. Stigma with an elongated, deeply divided point. Follicles . . . .

1. O. *fragrans*. The only ſpecies, diſcovered by ſir Joſeph Banks, in 1768, near Rio de Janiero. This is a twining *ſhrub*, with oppoſite heart-ſhaped *leaves*. *Umbels* between the *footſtalks*, ſomewhat corymboſe. *Flowers* ſweet-ſcented.

OXYPHLEGMASIA, from οξυς, and φλεγω, *to burn*, in *Surgery*, a very ſevere inflammation.

OXYPYCNI, οξυπυκνοι, in the ancient *Greek Muſic*, was a name given to ſuch chords as formed the higheſt ſounds of the ſpiſſa. There were five oxypycni in the ſcale. See PYCNI and SPISSUM.

OXYREGMIA, οξυρεγμια, formed from οξυς, and ερευγω, *ructo*, in *Medicine*, a ſourneſs of the ſtomach-liquor, occaſioning acid belches. See RUCTATION.

OXYRINCHITES, in *Ancient Geography*, a nome of Egypt, in Heptanomia, to the left of the Nile, on the borders of Libya.

OXYRINCHUS, a town of Egypt, the capital of the preceding nome, which took its name from a fiſh, called by the Greeks οξυρυγχος, oxyrynchus, which was an object of worſhip to the Egyptians, and which had a temple in this nome. This city became epiſcopal, and was much celebrated in the earlier ages of the church. Baillet ſays, that it contained 20,000 nuns and 10,000 monks, whence we may infer that the remaining population was very numerous, but this eſtabliſhment contributed, in proceſs of time, to the diminution of the inhabitants, and the decline of the place. Nothing remains of this city, in the village called Beneſech, built on its ruins, but ſome fragments of ſtone pillars, marble columns in the moſques, and a ſingle column left ſtanding, along with its capital, and parts of the entablature, which ſhew that it is the fragment of a portico of the Compoſite order. Thus, Oxyrinchus, once a metropolis, ſurrounded by a fertile plain, two leagues off the Libyan range of hills, has diſappeared beneath the ſand; and the new town has been obliged to retreat from this defolating invaſion, leaving to its ravages houſe after houſe; and the inhabitants muſt at laſt be driven beyond the canal Juſef, on the border of which they will be ſtill menaced. Denon's Travels in Egypt, vol. i.

OXYRRHODON, OXYRRHODINUM, compoſed of οξυς, *ſour*, and ῥοδον, *roſe*, a mixture of two parts of oil of roſes, and one part of vinegar, ſtirred together for ſome time.

To theſe are ſometimes added diſtilled waters. It is uſed for inflammations, and to dry up tetters.

Sculletus preſcribes it as follows: two whites of eggs beaten, one ounce and a half of vinegar of roſes, four ounces of roſe-water, and two ounces of oil of roſes.

OXYRYNCHUS, in *Ichthyology*, a ſpecies of *Raja*, which ſee.

OXYS, in *Botany*, οξυς, *ſharp* or *acrid*, ſee OXALIS.

OXYSACCHARUM, οξυσακχαρον, compounded of οξυς, *ſour*, and σακχαρον, *ſugar*, a liquid medicine, compoſed of ſugar and vinegar.

The name is more peculiarly given to a ſyrup prepared with vinegar, the juice of ſour pomegranates and ſugar; uſed to cool, refreſh, and reſiſt the malignity of peccant humours.

OXYSAL DIAPHORETICUM, the name of a compound medicine greatly recommended by ſeveral authors, and invented by Angelus Sala. The manner of preparing it is this: take fine ſalt of carduus benedictus, put it into an earthen pot, and pour upon it gradually ſome ſtrong wine-

vinegar,

vinegar, or ſpirit of ſugar; continue to pour this on till the ebullition ceaſes, and an agreeable ſmell ariſes, and the matter has an agreeable, though ſomewhat acid, taſte; let all the humidity from this mixture be evaporated over a gentle heat; and after this, let all the ſalt be again diſſolved in water, and ſet in digeſtion in balneo Mariæ for eight days: a liquor of a beautiful and pellucid colour is there produced, which, when poured carefully off into another veſſel, is to be again evaporated to a dryneſs with a very gentle heat, and the remaining matter, which is the ſalt, is to be collected together, and kept in a phial carefully ſtopt; for it is ſubject to run, if left to the acceſs of the air, like the common alkali ſalt.

OXYSTELMA, in *Botany*, ſo named by Mr. Brown, from οξυς, *ſharp*, and στελμα, the ſame as στεμμα, *a crown*; Brown in Tr. of the Wernerian Soc. v. 1. 40. Prodr. Nov. Holl. v. 1. 462. Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocyneæ*, Juſſ. *Aſclepiadeæ*, Brown.

Eſſ. Ch. Corolla wheel-ſhaped, ſpreading. Column prominent. Crown of the ſtamens of five compreſſed, acute, undivided leaves. Anthers tipped with a membrane. Maſſes of pollen compreſſed, attached by their taper points, pendulous. Stigma pointleſs. Follicles ſmooth. Seeds comoſe.

1. O. *eſculentum*. (Periploca eſculenta; Linn. Suppl. 168. Roxb. Coromand. v. 1. 13. t. 11. Willd. Sp. Pl. v. 1. 1250. Apocynum maderaſpatanum anguſtifolium ſcandens, flore amplo gemello verſicolore; Pluk. Amalth. 19. t. 159. f. 6, bad.)—Leaves linear-lanceolate. Segments of the corolla triangular.—Native of buſhy places, near rivers and pools, in Ceylon and Malabar. Koenig, who ſent fine ſpecimens to Linnæus, has written on one of them that "the plant is eſculent, and called *Uſepale* in the Tamul language." Dr. Roxburgh could not find that it was eaten by the people, at leaſt of the Malabar coaſt. He gives *Oudy-palla* as its name among the Telingas, and remarks that cattle eat it. The *root* is fibrous, and perennial as well as the twining, ſlender, ſmooth, round, branching *ſtems*. The *leaves* and *flowers* are produced during the rainy ſeaſon; the former are oppoſite, ſtalked, above two inches long, linear-lanceolate, acute, entire, ſmooth, ſingle-ribbed, light green, rounded at the baſe, deciduous. *Cluſters* long, lax, ſtalked, lateral, ſolitary, between the leaf-ſtalks at one ſide. *Flowers* the ſize of thoſe of *Primula Auricula*, of ſome of whoſe moſt beautiful varieties they give no very remote idea, but their ſegments are much more acute. Their colour is a pale bluſh, with crimſon veins, a purple eye, and a mixture of green and white in the centre.

2. O. *carnoſum*. Brown Prodr. Nov. Holl. v. 1. 462.—Leaves nearly oval, pointed. Segments of the corolla linear.—Native of the tropical part of New Holland, where it was obſerved by Mr. Brown. The *ſtems* are twining, herbaceous. *Leaves* fleſhy, ſmooth, oppoſite. *Flowers* in umbellate ſtalked cluſters, from between the leaf-ſtalks. Mr. Brown remarks that this New Holland ſpecies is ſo very different from the Eaſt Indian one, he is inclined to think they ought to be different genera.

OXYTOCHIA, formed of οξυς, *ſharp*, and τικτω, *I bring forth*, in *Medicine*, a term uſed by many authors to expreſs ſuch medicines as are given to promote delivery.

OYACACHA, in *Geography*, a town of South America, in the province of Quito; 25 miles E. of Quito.

OYAMBRE, Cape, a cape on the N. coaſt of Spain. N. lat. 43° 25′. W. long. 4° 17′.

OYAPOOK, a river of Guiana, which runs into the Atlantic, near cape Orange.

OYE, a town of France, in the department of the ſtraits of Calais, ſituated on a branch of the river Aa, to which it gives name, formerly in poſſeſſion of the Engliſh; ſeven miles E.N.E. of Calais.

Oye, *Norder* and *Sander*, two ſmall iſlands of Denmark, in the North ſea, two and three miles N. of Nordſtrand.

OYER, a town of Norway; 88 miles N. of Chriſtiania.

Oyer ſeems to have been anciently uſed for what we call *aſſizes*.

Oyer *and terminer*, a commiſſion directed to the judges and other gentlemen of the county to which it is iſſued, by virtue whereof they are empowered to hear and determine treaſons, and all manner of felonies and treſpaſſes. However, the judges or ſerjeants at law only are of the *quorum*, ſo that the reſt cannot act without the preſence of one of them. The term is French, and literally denotes to hear and determine. In our ſtatutes it is ſometimes written *oyer and determiner*. This is the firſt and largeſt of the five commiſſions by which our judges of aſſize do ſit, in their ſeveral circuits. (See Assizes.) The words of the commiſſion are "to inquire, hear, and determine;" ſo that by virtue of this commiſſion they can only proceed upon an indictment found at the ſame aſſizes, for they muſt firſt inquire, by means of the grand jury or inqueſt, before they are empowered to hear and determine by the help of the petit jury. Therefore they have another commiſſion of "gaol-delivery," which empowers them to try and deliver every priſoner, who ſhall be in the gaol when the judges arrive at the circuit town, whenever, or before whomſoever indicted, or for whatever crime committed. Thus, one way or other, the gaols are in general cleared, and all offenders tried, puniſhed, or delivered, twice in every year. Sometimes alſo, upon urgent occaſions, the king iſſues a ſpecial or extraordinary commiſſion of oyer and terminer, and gaol-delivery, confined to thoſe offences, which ſtand in need of immediate inquiry and puniſhment; upon which the courſe of proceeding is much the ſame, as upon general and ordinary commiſſions. Formerly it was held, in purſuance of the ſtatutes 8 Ric. II. c. 2. and 33 Henry VIII. c. 4. that no judge or other lawyer could act, in the commiſſion of oyer and terminer, or in that of gaol-delivery, within his own county, where he was born or inhabited; in like manner as they are prohibited from being judges of aſſize and determining civil cauſes. But that local partiality, which the jealouſy of our anceſtors was careful to prevent, being judged leſs likely to operate in the trial of crimes and miſdemeſnors, than in matters of property, and diſputes between party and party, it was thought proper by the ſtatute 12 Geo. II. c. 27. to allow any man to be a juſtice of oyer and terminer, and general gaol-delivery, within any county of England.

Anciently it was only in uſe upon ſome ſudden outrage, or inſurrection, in any place.

Oyer *de Record* is a petition made in court, praying that the judges, for better proof-ſake, will be pleaſed to hear, or look upon, any record.

In the like ſenſe, a perſon may demand *oyer* of a bond, deed, covenant, or the like.

O YES, a corruption of the French *oyez*, *hear ye*, being a term, or formula, wherein the criers in our courts enjoin ſilence or attention, before they make proclamation of any thing.

OYL Creek, in *Geography*, a river of Pennſylvania, which runs into the Allegany, N. lat. 41° 26′. W. long. 72° 43′.

OYON, a town of Spain, in the province of Alava; 22 miles S.S.E. of Vittoria.

OYONNEZ, a town of France, in the department of the Ain, and chief place of a canton, in the diſtrict of Nantua;

Nantua; ſeven miles N. of Nantua. The place contains 1178, and the canton 7278 inhabitants, on a territory of 207½ kiliometres, in 11 communes.

OYSTER, in *Natural Hiſtory*. See OSTREA.

Oyſters in their growth become faſtened to every ſolid ſubſtance which they happen to come into contact with; and rocks, ſmall ſtones, wood, ſea-plants, and a thouſand other things, are found at times with oyſters adhering to them, whoſe ſhells have fitted themſelves to the form of the thing itſelf, and loſt their natural ſhape. The people who fiſh for, and trade in oyſters, pretend to diſtinguiſh two kinds; one which is fecund, and will breed; the other, which is barren. They ſay, they diſtinguiſh theſe by a little black fringe, which always ſurrounds the good breeding oyſters.

The way to make oyſters green is, to put them into ſmall pits where the water is about three feet deep, in the ſalt marſhes, and where the ſun has great power; in theſe they become green in three or four days.

The oyſter affords the curious in microſcopic obſervations a very pleaſing entertainment. In the clear liquor many little round living animalcules have been found, whoſe bodies being conjoined, form ſpherical figures, with tails not changing their place otherwiſe than by ſinking to the bottom, as being heavier than the fluid; theſe have been ſeen frequently ſeparating, and then coming together again. In other oyſters, animalcules of the ſame kind were found, not conjoined, but ſwimming by one another, whence they ſeemed in a more perfect ſtate, and were judged by Mr. Leewenhoeck to be the animalcules in the roe or ſemen of the oyſter.

A female oyſter being opened, incredible multitudes of ſmall embryo oyſters were ſeen, covered with little ſhells, perfectly tranſparent, and ſwimming along ſlowly in the liquor; and in another female the young ones were found of a browner colour, and without any appearance of life or motion.

Monſieur Joblot alſo kept the water running from oyſters three days, and it appeared full of young oyſters ſwimming about nimbly in it; theſe increaſed in ſize daily, but a mixture of wine, or the vapour of vinegar, killed them.

In the month of Auguſt oyſters are ſuppoſed to breed, becauſe young ones are then found in them. Mr. Leewenhoeck, on the fourth of Auguſt, opened an oyſter, and took out of it a prodigious number of minute oyſters, all alive, and ſwimming nimbly about in the liquor, by means of certain exceeding ſmall organs, extending a little way beyond their ſhells; and theſe he calls their beards. In theſe little oyſters he could diſcover the joinings of the ſhells, and perceived that there were ſome dead ones, with their ſhells gaping. Theſe, though ſo extremely minute, are ſeen to be like the large oyſters in form.

As to the ſize of them, he computes, that a hundred and twenty of them in a row would extend an inch; and, conſequently, that a globular body, whoſe diameter is an inch, would, if they were alſo round, be equal to a million ſeven hundred and twenty-eight thouſand of them. He likewiſe found animalcules in the liquor five hundred times leſs than the embryo oyſters. Leewenhoeck, Arcan. Nat. tom. iv. p. 513.

It is not very uncommon to ſee on oyſter-ſhells, when in a dark place, a ſhining matter or blueiſh light, like a flame of brimſtone, which ſticks to the fingers when touched, and continues ſhining and giving light for a conſiderable time, though without any ſenſible heat. This ſhining matter being examined with a microſcope, was found to conſiſt of three different ſorts of animalcules. Phil. Tranſ. N° 279. See OYSTER-*worm*, infra.

From another account, preſerved in Sprat's Hiſtory of the Royal Society, from p. 307 to 309, we learn that the oyſters caſt their ſpawn, which the dredgers call their ſpat, in the month of May; this ſpat cleaves to ſtones, old oyſter-ſhells, pieces of wood, &c. at the bottom of the ſea, which they call cultch; and it is conjectured, that the ſpat in twenty-four hours begins to have a ſhell. In the month of May, the dredgers, by the law of the admiralty court, have liberty to take every kind of oyſter, whatſoever be their ſize. When they have taken them, they gently raiſe with a knife the ſmall brood from the cultch, and then they throw the cultch in again, to preſerve the ground for the future, unleſs they be ſo newly ſpat, that they cannot be ſafely ſevered from the cultch: in this caſe they are permitted to take the ſtone or ſhell, &c. which the ſpat is upon, one ſhell having often twenty ſpats. After the month of May, it is felony to carry away the cultch, and puniſhable to take any other oyſters, except thoſe of the ſize of a half-crown piece; or ſuch as, when the two ſhells are ſhut, will admit of a ſhilling to rattle between them. This brood, and other oyſters, are carried to creeks of the ſea, and thrown into the channel, which are called their beds or layers, where they grow and fatten; and in two or three years the ſmalleſt brood will become oyſters of the foreſaid ſize. There are great penalties, impoſed by the admiralty court, upon thoſe that fiſh out of the grounds which the court appoints, or that deſtroy the cultch, or that take any oyſters that are not of the proper ſize, or that do not deſtroy a fiſh, which they call the five-finger, the common ſea-ſtar, becauſe that fiſh gets into the oyſters when they gape, and ſucks them out. The reaſon of the penalty for deſtroying the cultch is, that they find when this is taken away, the ouſe will increaſe, and the muſcles and cockles will breed there, and deſtroy the oyſters, becauſe they have no convenience for depoſiting their ſpat. The oyſters are ſick after they have ſpat; but in June and July they begin to mend, and in Auguſt they are perfectly well: the male oyſter is black-ſick, having a black ſubſtance in the fin; and the female white-ſick, as they term it, having a milky ſubſtance in the fin. Oyſters are ſalt in the pits, ſalter in the layers, and ſalter at ſea. It is obſerved, that when the tide comes in, they lie with their hollow ſhell downwards, and when it goes out, they turn on the other ſide; they do not remove from their places, except in cold weather to cover themſelves in the ouſe.

OYSTER *Fiſhery*. See FISHERY.

OYSTERS, *Foſſile*. The greateſt bed of foſſile oyſters any where known is that near Reading, in Berkſhire. They have the entire ſhape, figure, and are of the ſame ſubſtance with the recent oyſter-ſhells, and yet muſt have lain there for a long time, the oldeſt hiſtories that mention the place giving an account of them. They are extended over no ſmaller a ſpace than ſix acres of ground, and juſt above them there is a large ſtratum of a greeniſh loam, called by ſome writers a green earth, and by others a green ſand. It is compoſed of a crumbly marle, and a very large portion of ſand. Under them there is a thick ſtratum of chalk. They all lie in a level bed, and the ſtrata above the ſhells are natural, and have never been dug through till the time of finding the ſhells.

The oyſter-ſhells and green earth together make a ſtratum of about two feet thick; and over this a much thicker ſtratum, of a blueiſh and very brittle clay; but this has never been dug through, except where we find the ſhells. The people call this *piercy-clay*, and ſay it is fit for no uſe. This bed of clay is about a yard deep, and above it is a ſtratum of fuller's earth, about two feet and a half deep; it is of a very good kind, and is uſed by the clothiers. Over this there lies a ſtratum of a fine white ſand unmixed either with

the clay or fuller's earth: this is near ſeven feet deep, and above this there is a ſtratum of a ſtiff red clay, of which they make tiles in the place. This is covered with a little vegetable mould, and the depth of this ſtratum of tile-clay cannot be aſcertained, becauſe of the unevenneſs of the hill.

Theſe oyſters are ſometimes found whole, but more uſually in ſingle ſhells. When they are in pairs, there is uſually ſome of the green ſand found within them: they ſeldom ſtick very faſt together; ſo that unleſs very carefully taken up, it is not eaſy to get them in pairs. Phil. Tranſ. N° 261. p. 484.

Oyster-*Shells*. Theſe are an alkali of a more powerful kind than is commonly ſuppoſed, and probably are in reality much better medicines than many of the more coſtly and pompous alkalis of the ſame claſs. The proof of alkalis is in their ſolution by acid ſpirits; and Mr. Homberg found, that they diſſolved much more eaſily in the acids of nitre and ſea-ſalt than pearls, coral, and the reſt; which he ſuppoſes owing to their containing in the body of the ſhell a conſiderable portion of ſal-ſalſus, which is eaſily perceived upon the tongue, and which keeps the whole ſubſtance of the ſhell in a ſort of half-diſſolved ſtate. Theſe ſhells are found to produce very great effects on the ſtomach, when injured by acid humours; and Mr. Homberg is of opinion that this their eaſineſs of ſolution is one great reaſon of their good effects, and that the quantity of ſal-ſalſus which they contain, contributes not a little towards it, ſince we are not to look upon that as a mere ſalt, but a ſalt of a peculiar kind, formed of ſea-ſalt by the organs of the animal, and the ſeveral fermentations it undergoes in the body of it, in the ſame manner as the nitrous and other ſalts of the earth ceaſe to be nitrous, &c. as ſoon as they have been blended with the juices of plants, and form with them a ſalt peculiar to that plant; and this is plainly the caſe in regard to this ſalt, ſince it is evidently of a more penetrating taſte, and of a different ſmell, from the ſalt left by the ſea-water between the ſeveral external ſcales, or flakes of the ſhell.

As oyſter-ſhells were found by Mr. Homberg to be a very valuable medicine, and as one of the common methods of preparing them is by calcination, which he obſerves cannot but much impair their virtues, he gives the following method of preparing them for taking inwardly, which was what he always uſed.

Take the hollow ſhells of the oyſters, throwing away the flat ones as not ſo good; waſh them perfectly clean, and then lay them to dry in the ſun: when they appear dry, beat them to pieces in a marble mortar, they will be then found to contain yet a large quantity of moiſture; lay them again in the ſun till perfectly dried, and then finiſh the powdering them, and ſift the powder through a fine ſieve. Give twenty or thirty grains of this powder every morning, and continue it three weeks or a month. Mem. Acad. Par. 1700.

For the method of calcining oyſter-ſhells, and thus preparing a phoſphorus, ſee *Canton's* Phosphorus.

Oyster-*Worm*, in *Natural Hiſtory*, a name given by writers to a kind of ſmall worm found in oyſters, which ſhines in the dark, in the manner of the glow-worm; but with an univerſal light, and not in a peculiar part only.

The firſt obſerver of theſe oyſter-worms was M. De Lavoye, who communicating his obſervations to M. Auzout, gave occaſion to a very diſtinct account of them from this author.

The firſt thing that preſents itſelf, on the opening of the oyſters which contain theſe worms, is only a ſort of ſhining clammy moiſture, which appears like a ſtar of a blueiſh colour, and, being drawn out, will extend itſelf to near half an inch long, and ſhine as much for that whole length as in the contracted ſtate: it will alſo ſhine for ſome time after it is taken out of the oyſter.

On a ſtricter obſervation, theſe ſhining ſubſtances are found to be real living worms, and there are indeed three diſtinct ſpecies of them. One ſort is whitiſh, and has twenty-four or twenty-five feet on each ſide: there is a black ſpeck on one ſide the head, and the back exactly reſembles that of an eel, when the ſkin is ſtripped off. The black ſpeck in the head is certainly an eye; and it is remarkable that the creature has but one. The ſecond ſort of theſe worms is red: this alſo has but one eye; its body is made up of ſeveral rings; its noſe is like that of a dog, and it has the ſame number of feet with the former. The third ſort is very different from the other two: it is ſpeckled, and its head is like that of a foal, and has a tuft of hair on each ſide. There are other worms found alſo in the oyſter, particularly a large greyiſh one, with two horns, a great head, and ſeven or eight whitiſh feet; but theſe do not ſhine. This light occurs more frequently in large than in ſmall oyſters; there are few of theſe large ones that do not yield it in the ſhells, and in ſome it is ſeen in the oyſters themſelves. Journal de Sçavans, 1666.

Oyster *Bay*, in *Geography*, a townſhip of New York, ſituated in Queen's county, Long Iſland, extending from the ſound ſouth to the Atlantic ocean, and including Lloyd's Neck or Queen's village and Hog iſland. It contains 4548 inhabitants, of whom 134 are ſlaves.

Oyster *Bay*, a harbour for ſmall veſſels, in the ſouth-weſt limits of Barnſtable, Maſſachuſetts. It derives its name from its excellent oyſters.

Oyster *Creek*, a river of North Carolina, which runs into the Atlantic, N. lat. 34° 50′. W. long. 76° 45′.—Alſo, a river of New Jerſey, which runs into the Atlantic, N. lat. 39° 44′. W. long. 74° 20′.

Oyster *Harbour*, a bay on the ſouth-weſt coaſt of New Holland, and north part of King George the Third's Sound, diſcovered by captain Vancouver in the year 1791, and ſo called from its plenty of oyſters. It is rendered admiſſible only for veſſels of a middle ſize, by the ſhallowneſs of the water on the bar, extending from ſhore to ſhore, on which were found only 17 feet of water, although the depth increaſed from five to ſeven fathoms on each ſide. The deep water within this harbour did not ſeem to be of any great extent. In both theſe harbours the communication with the country is rendered unpleaſant, by the ſhallow depth of water extending to a great diſtance from the ſhore. If it ſhould be thought an object of importance, this inconvenience might be eaſily remedied by wharfs. S. lat. 36° 58′. E. long. 118° 15′.

Oyster *Haven*, one of the numerous bays on the ſouth-weſt coaſt of Ireland, in the county of Cork. The entrance is about two miles eaſtward of Kinſale harbour. It is ſeldom frequented, being too near the much ſuperior harbours of Cork and Kinſale; but there is good ſhelter for ſmall veſſels. M'Kenzie.

Oyster *Iſland*, an iſland in the bay of Bengal, near the coaſt of Aracan. N. lat. 20° 13′. E. long. 92° 43′.—Alſo, a ſmall iſland in the bay of Sligo, Ireland, between which and the land is the only place in the harbour where a veſſel can ride afloat at all hours of the tide. This is diſtinguiſhed by the name of Oyſter iſland harbour, and has well-ſheltered anchorage. M'Kenzie.

Oyster *Iſland Harbour*, a bay or harbour on the Atlantic, on the coaſt of Maſſachuſetts. N. lat. 41° 35′. W. long. 70° 24′.

OYSTER *River*, a ſandy bay, within the ſouth head of Mercury bay, in New Zealand.

OYSTER *River*, a branch of the Piſcataqua, in New Hampſhire.

OYSTERMOUTH, a ſea-port and pariſh in the cwmwd of Gwyr, cantref of Eginoy (now called the hundred of Swanſea,) and county of Glamorgan, South Wales, is ſituated on a ſmall promontory, which forms the weſtern boundary of Swanſea bay, in the Briſtol channel. The eaſtern extremity of the pariſh is called "The Mumble Point," oppoſite to which, at a ſhort diſtance from the ſhore, a light-houſe has been lately erected. This place might be made an excellent ſtation for ſhipping at a very trifling expence, either by walling in the ſounds between the Mumble Head and the ſhore, or by running a pier out under the eaſt point of Mumble Hill. Veſſels bound for Falmouth with coals from Swanſea generally lie here when waiting for wind and convoy; frequently to the number of one hundred and fifty ſail at one time. Along the ſhore hence to Swanſea, a railway has been conſtructed, by which coals and manure are brought down, and lime returned from the limeſtone quarries, which are ſituated cloſe to the village of the Mumbles, and where ſeveral lime-kilns are eſtabliſhed. In digging the ſtone of theſe quarries many human bones of large dimenſions have been diſcovered; and tradition ſays, this ſpot was formerly the ſcite of a chapel, but no veſtiges of it now remain. The exiſtence of ſuch a building, however, is not improbable, as the ſea has made great encroachments on this part of the bay. A large wood, called "Crow's Wood," frequently mentioned in ancient records, has been ſubmerged, and traces of it are ſtill evident in the ſand at low water. Vaſt quantities of ſhell-fiſh, but particularly oyſters, are caught or dragged on the coaſt here: hence the origin of the term Oyſtermouth as the deſignation of the pariſh, which, according to the parliamentary returns of 1811, contains 200 houſes and 761 inhabitants.

On a knoll or eminence eaſt from the church ſtand the ruins of Oyſtermouth caſtle, ſuppoſed to have been erected by the Norman Beaumonts, who conquered Gowerland. It has ſuffered leſs from the ravages of time than any ruin in this part of the country, the principal walls being as yet in good condition, and moſt of the apartments entire. The general figure is polygonal, and the ramparts are conſpicuouſly lofty, but there are no flanking towers except on each ſide of the entrance gateway. Here, according to tradition, the chancery court for the ſeignory of Gower was anciently held. This edifice is now the property of the duke of Beaufort, as lord of the ſeignory, and is much reſorted to by parties of pleaſure from Swanſea and the neighbourhood. In one of the dungeons of the caſtle is a circular ſtone pillar, into which almoſt every viſitor ſticks a pin, conformably to an old cuſtom, practiſed from time immemorial. The whole ruin is covered with a profuſion of ivy.

Weſtward from Oyſtermouth is the pariſh of Pen-Arth, part of which is conjectured to have been anciently the ſcite of a conſiderable town, as many foundations of houſes are dug up among the ſands, and there is ſtill a village to the ſouth of them, called "South-gate," and alſo a farm houſe to the north, called "Norton" or "North-Town." Here are alſo very extenſive remains of a caſtle ſituated near the mouth of a ſmall rivulet, which divides the pariſh of Pen-Arth from that of Pen-Maen. The gateway is almoſt entire, and is a very fine ſpecimen of ancient architecture. Between this fortreſs and the ſea, on the ſands, is a rock, called "The Three Cliffs," from its reſemblance to three ſugar loaves placed in a line. In the centre of this rock is a curiouſly formed arch, ſuppoſed to have been excavated by the ſea; and not far from hence is a ſingular cavern in the cliff, called "Bacon's Hole." This cavern is ſituated nearly midway between the water and the ſummit of the rock, and is inacceſſible from below in any ſtate of the tide, but there is a narrow and very ſteep path leading down to it from above, by which, though the attempt is fraught with the utmoſt danger, many perſons deſcend. Carliſle's Topographical Dictionary of Wales, 1 vol. 4to. 1811.

OZÆNA, in *Surgery*, from ὀζη, *a fetid ſmell*, uſually ſignifies a fetid ulcer, when ſituated within the cavity of the noſe, and frequently accompanied with caries.

This diſeaſe, in the early ſtate, is ſometimes attended with many of the common ſymptoms of a catarrh. As Mr. Pearſon remarks, a trifling ſwelling and redneſs take place about the ala naſi, accompanied with a diſcharge of mucus. The air is tranſmitted through the affected noſtril with difficulty, eſpecially during ſleep; and, in the morning, the orifice is often quite obſtructed by mucus. As the diſeaſe advances, the diſcharge aſſumes more of a purulent appearance, and it is moſt abundant in the morning. Sneezing and ſlight hemorrhages occaſionally happen. The ulceration often extends outwardly, ſpreading round the ala naſi over the cheek; but it hardly ever deſtroys the ala naſi, or ſpreads far from the noſe.

This diſeaſe is deſcribed by Mr. Pearſon as being frequently connected with ſcrofula and venereal complaints; and he ſtates, that in the latter caſe, more frequently than in the former, carious portions of the oſſa ſpongioſa come away. Many venereal patients, whoſe complaints have been properly treated, ſometimes complain of a diſcharge of fetid matter from the noſtrils, and of troubleſome incruſtations within the cavities, for a conſiderable time after the perfect cure of their original diſeaſe. According to the preceding writer, theſe ſymptoms generally indicate the preſence of carious bone; and when that has exfoliated, the complaints will ceaſe.

The ozæna frequently occurs as a ſymptom of cachexia ſyphiloidea. It will perforate the ſeptum naſi, deſtroy the oſſa ſpongioſa, and ſometimes render the oſſa naſi completely carious. The depreſſion of the noſe, from the loſs of the oſſa naſi, is, according to Mr. Pearſon, more frequently the effect of the cachexia ſyphiloidea, at the preſent day, than of lues venerea.

As abſceſſes of the antrum are attended with ſome ſymptoms, which reſemble thoſe of the ozæna, the ſurgeon muſt be upon his guard againſt miſtaking one diſeaſe for the other.

When the ozæna is altogether a local diſeaſe, as it muſt be regarded, when entirely kept up by the preſence of a dead portion of bone, that has not yet exfoliated, conſtitutional remedies appear to be unneceſſary. The dead bone will in time be caſt off, and the ſore ſpontaneouſly heal. But, in every inſtance, the utmoſt care muſt be taken to keep the part affected as clean as poſſible; and, with this view, alum and zinc injections are proper.

When ozæna, however, is dependent upon a ſcrofulous affection of the conſtitution, upon lues venerea, or what is termed the cachexia ſyphiloidea, the particular remedies for theſe particular ſtates of the ſyſtem muſt be given, ere the ulcer can be cured.

The principal internal medicines, employed for the cure of the ozæna, are,

1. Preparations of mercury, or antimony.

2. Sarſaparilla, elm-bark, Peruvian bark, muriate of barytes, muriate of lime.

3. Sea-

3. Sea-bathing.

The beſt topical applications are,

Preparations of copper, zinc, arſenic, mercury, pulvis ſternutatorius, mercurial fumigations, diluted ſulphuric acid, &c. See Pearſon's Principles of Surgery, edit. 2. p. 285; 286.

OZAMA, in *Geography*, one of the largeſt rivers of Hiſpaniola, on which St. Domingo is ſituated near its diſcharge into the ſea. It is navigable nine or ten leagues from ſouth to north. At the mouth there is a rock, which prevents the entrance of veſſels that draw more than 18 or 20 feet of water. The road before the mouth is very indifferent, and lies expoſed from W.S.W. to E. It is impoſſible to anchor in it in the time of the ſouth winds, and the north winds drive the veſſels from their moorings into the ſea, which here runs very high. The mouth of the river is in N. lat. 18° 18′, and W. long. 72° 38′ from Paris.

OZANAM, James, in *Biography*, an eminent French mathematician, who flouriſhed in the 17th and 18th centuries, was deſcended from a family of Jewiſh extraction, but which had long ſince profeſſed the Chriſtian faith, and ſome of the branches of it had held different offices in the parliament of Provence. He was born in the year 1740, and being intended for the church, his courſe of education was adapted to his future profeſſion. He became, however, enamoured with mathematical ſtudies, and ſo ſucceſsful was he in this purſuit, that, at the age of fifteen, he wrote a ſort of mathematical treatiſe, which was never printed, but contained many things which he thought proper to inſert in the works that he afterwards publiſhed. On the death of his father, he devoted himſelf entirely to the ſciences, and ſoon afterwards went to Lyons, where he commenced mathematical tutor for his ſupport, obtained many pupils, and a conſiderable ſhare of reputation. Here he acquired a paſſion for gaming, but was, upon the repreſentation of a good friend, perſuaded to go to Paris, where he extricated himſelf from the habit which he had formed at Lyons, and became highly reſpected for his manners, his various talents, and learning. For ſeveral years he derived a conſiderable income, from teaching the mathematics at Paris. In 1701 he had the misfortune to loſe his wife, with whom he had lived moſt happily many years, and by whom he had twelve children. This circumſtance, added to ſome others that were very diſtreſſing, reduced him to a ſtate of melancholy, from which he was in a good meaſure recovered by the honour of being admitted, in the ſame year, an *elève* of the Royal Academy of Sciences. He died in 1717, at the age of 77. M. Ozanam was uſually diſtinguiſhed by a mild and calm diſpoſition, a cheerful temper, which manifeſted itſelf under many heavy and very accumulated diſtreſſes. He was ſincerely pious and devout, but ſtudiouſly avoided all theological controverſy, and was accuſtomed to ſay, when urged on that topic, "that it was the buſineſs of the Sorbonne to diſcuſs, of the pope to decide, and of the mathematician to go to heaven in a right line." He publiſhed a great number of uſeful books, chiefly introductory to the ſciences; among which were "A Courſe of Mathematics, comprehending all the moſt uſeful and neceſſary Branches of this Science," in 5 vols.; "A Treatiſe on Fortification, containing the ancient and modern Methods of the Conſtruction and Defence of Places," 4to.; "Mathematical and Philoſophical Recreations, containing numerous, uſeful, and pleaſing Problems in Arithmetic, Geometry, Optics," in 2 vols. 8vo.

OZAR, in *Geography*, a town of Perſia, in the province of Segeſtan; 62 leagues S.E. of Zareng.

Ozar, a town of Italy, in the principality of Piedmont; 10 miles S. of Turin.

OZE, a word uſed by ſome writers to expreſs a fœtor, or ill ſmell of the mouth.

OZEMAN, in *Geography*, a town of Aſiatic Turkey, in the province of Natolia, between Amaſieh and Tocat.

OZENE, in *Ancient Geography*, a name given in the Periplus of the Ærythrean ſea, as well as in Ptolemy, to the city now called *Ougein*; which ſee.

OZERNAIA, in *Geography*, the name of two fortreſſes of Ruſſia, in the government of Upha, on the Ural; one 40 miles W. of Orenburg, and the other 64 miles E. of it.

OZERNOVSKOI, a cape of Ruſſia, on the eaſtern coaſt of Kamſchatka; 32 miles N.E. of Ukinſkoi.

OZIGINA, an oſtrog of Ruſſia, on the Indigirda; 144 miles N.N.E. of Zaſhiverſk. N. lat. 69° 30′. E. long. 142° 22′.

OZINO, a town of Japan, in the iſland of Niphon; 25 miles N. of Meaco.

OZINOVSKOI, a town of Ruſſia, in the government of Perm, on the Kama; 16 miles N.N.E. of Oſa.

OZMA, a town of Bulgaria, on a river of the ſame name; 21 miles S. of Nicopoli.

OZOHOWK, a town of Poland, in Volhynia; 14 miles S.S.E. of Kreminick.

OZOLAVA, one of the larger Navigator's iſlands, in the South Pacific ocean; the inhabitants of which greatly reſemble thoſe of Maouna. S. lat. 14°. W. long. 171° 25′.

OZOPHYLLUM, in *Botany*, a genus of Schreber's, the name of which is derived from *οζω, to ſtink*, and *φυλλον, a leaf*, in alluſion to the unpleaſant ſcent of its foliage when bruiſed. Schreb. 452. Willd. Sp. Pl. v. 3. 585. Mart. Mill. Dict. v. 3. (Ticorea; Aubl. Guian. v. 2. 689. Cavan. Diſſ. 6. 362. Juſſ. Gen. 264.)—Claſs and order, *Monadelphia Pentandria*. Nat. Ord. *Meliæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very ſmall, five-toothed, acute. *Cor.* Petals five, their long claws united into the form of a tube; their limbs oblong, obtuſe, ſpreading. *Stam.* Filament cylindrical, ſheathing the ſtyle, five-toothed at the apex; anthers five, oblong, erect. *Piſt.* Germen ſuperior, five-lobed, ſurrounded by a gland; ſtyle thread-ſhaped, longer than the petals; ſtigma capitate. *Peric.* five-celled. *Seeds* unknown.

Eſſ. Ch. Calyx five-toothed. Corolla funnel-ſhaped, of five petals. Style one. Capſule? five-celled.

1. O. *fœtidum.* Mart. Mill. Dict. (O. trifoliatum; Willd. Ticorea fœtida; Aubl. Guian. t. 277. Cavan. Diſſ. t. 206.)—This ſolitary ſpecies of *Ozophyllum* is a native of the foreſts of Guiana, where it flowers in February. *Stem* ſhrubby, about ten or twelve feet in height, much branched, covered with a ſmooth, green bark. *Leaves* alternate, digitate, on long ſtalks; leaflets three, the central one larger, all ſmooth, ſoft, oval, ſharp-pointed. *Flowers* terminal, corymboſe, white.

Willdenow has changed the ſpecific name to *trifoliatum*, but ſince the whole plant, when bruiſed, emits a ſtrong diſagreeable ſmell, like that of *Stramonium*, we are induced to retain the original one of Aublet, notwithſtanding Schreber's generic name is expreſſive of its fœtid qualities. The wood of this ſhrub is deſcribed as white, tender, and fragile.

OZUNICZE, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 30 miles E.S.E. of Breſlaw.
